Dr W R Bion thought the subject was apt to be confused by the psychological conflicts of those entrusted with education and the confusion of instruction in the hygiene, anatomy, and physiology of reproduction with a vague attempt to solve the child's difficulties The two were not easily brought into relation The child had an arduous task, for he had to deal with a changing environment and changing and powerful feelings and sensations which could be aroused by events without or events within Nocturnal emissions added to the difficulty after puberty, and feelings of guilt and anxiety were also present and endowed by the child with objective validity The tone or atmosphere of home or school was most important Objective difficulties paled into insignificance when the child began to try to deal with his internal feelings and conflicts The child was highly selective and might remember one sermon holding up sex as horrible while he forgot a score of experiences to the contrary Dramatisation and objectification further complicated the situation, and others might seize on a child's dramatisation to solve their own conflicts Emotional maladjustment in teachers gravely affected their influence Homosexual masters punished what they regarded as homosexual indications, or mother tied pedagogues urged loyalty to the old school. A child often seemed to try and climb out of his difficulties with one foot in fantasy and one in external reality, it was nearly always the latter which crumbled. Some day educators might come to regard sex difficulties as a matter for education and not for discipline If only hygiene were involved the matter would be simple, but when a need for psychotherapy came in the stage was set for trouble Transference and counter transference provided dangerous elements Most unexceptional statements might be made, but the child would be aware of the emotional attitude behind them To hand a boy a book was to set apart sex problems as the only ones that would be dealt with in that way Any patching up of methods of sex education was likely to be a pernicious excuse for postponing an attack on the fundamental problem, which was the bedevilment of an almost simple matter of psychological development by the psychological parasitism of the adult By the time school age was reached, sex education had become not a liberating agent but a means whereby was added to his other burdens that of coping with an adult transference The problem must be looked upon not simply as one of transition from a bad system to a better but rather as a matter of putting an end to an activity that was positively harmful, and substituting for it one that was beneficent

Miss Barbara Low said that the love between the parents often stimulated jealousy in the child Knowledge should be a liberating thing—but there was another side to it The lesson of Genesis and of Œdipus Rex was that knowledge was a terrible, *dangerous, and alarming thing* To say that knowledge should only be given when asked was putting a great burden on the child, who often dare not ask or dare not face the knowledge he could have

Prof Thouless asked if Dr Bion thought that only psychologically trained persons should give instruction This would not be practicable as the first questions cropped up unexpectedly with parents How far was it true that any normal child would ask questions about sex between 3 and 5 ? Some children did not ask, what then should the parent do ?

Dr J A Hadfield said that children who had been instructed might completely forget and evolve a fantastic theory of their own He did not know what the inhibition was Perhaps a child of 3 did not like to feel it had had that intimate connexion with its mother

Dr Irene Yates thought teachers should have some knowledge of the underlying conflict before children were plunged into dissections after a few weeks at school. This often resulted in complete inhibition of any desire to know any more about biology or sex —Dr D N Hardcastle asked whether the inhibition against knowledge of intimate personal biology was *carried over to general biology*—Dr Yates replied that she had known such a case, a biology course in a medical school had brought up the personal conflicts in great intensity

Mr Harris, asked to define a "proper" attitude, said he meant one of perfect frankness about all bodily *functions, regarding them as part of the* ordinary machinery of life

Dr John Rickman could not understand the danger of knowledge Information could be given in a disturbing way, he knew, but that was not the same thing, and only partial information was disturbing Whole information—that which could be comprehended by the child—was not disturbing

Prof H R Hamley thought the keynote of the discussion was the naturalness of imparting natural information It did not help to tell a boy that wet dreams were natural, but it did help to make him *feel that if he regarded them as natural his tensions* would be relieved He agreed that the child sought knowledge rather than trying to flee from it, and that all knowledge should be treated in the same fearless way When the child felt confidence in the *adult he produced his questions*

The Chairman said that the problem of sex education could not be approached like anything else, it was entirely in a category by itself The average parent could not explain perfectly naturally to the average child. Every child approached the sex problem from a different point of view, which was why class instruction was such a miserable pis aller A large number, for reasons of all sorts and kinds, approached sex knowledge with enormous dread

The mere manner of some parents would dispel the anxiety which was the real problem; the actual information was not the important thing

Dr ISAACS in reply agreed that it was not the information but the emotional attitude that helped the child The ignorance of 9 10 11 was part of the natural emotional development of the child and changed again at 12 13 or 14 The stork had not been invented for nothing It was easier to think of the stork than the phallus Often parents who consciously would like to give information were unconsciously frightened and inhibited questions To initiate the subject the parent could provide a normal stimulus to questioning by such means as visits to babies or contact with animals. On the whole, jealousy was only serious if it succeeded in separating the parents When people felt that knowledge was harmful they did not mean knowledge but the unconscious deep meaning of the knowledge

Dr BION in reply thought the parental part was the most promising approach and that a happy marriage was most important Humility and affection could make up any amount of defects of technique Lying was always detected If ignorant parents would learn with the child they would find a valuable ally in their pupil

Mr HARRIS also in reply thought that even children who had been wrongly treated at home might be led by suitable school environment to realise the simplicity of the great subject of sex

ROYAL SOCIETY OF MEDICINE

SECTION OF EPIDEMIOLOGY

A MEETING of this section was held on Feb 20th with Surgeon Rear Admiral S F DUDLEY the president in the chair In a communication on the

Epidemiology of Weil s Disease

Dr J M ALSTON and Major H C BROWN said that in 1880 Adolf Weil of Heidelberg had described four cases of a form of infective jaundice which were so similar that he considered them to be of the same disease. In each there was a febrile illness with severe jaundice and signs of renal disease and after a severe illness of relatively short duration recovery was rapid Weil's belief that he had established a new entity was finally confirmed in 1915 when Inada of Japan demonstrated the causative organism now named *Leptospira ictero hæmorrhagiæ* The illness was well known at the time in Japan occurring in epidemic or endemic form and characterised by conjunctival congestion muscular pain fever jaundice hæmorrhagic diathesis albuminuria and a fairly high mortality rate this had been the usual form of the disease in all countries The leptospira was a highly flexible filament with very tightly wound and rather shallow spirals at each extremity it was bent over in the form of a hook The disease was widely distributed and it was likely that now easier methods of diagnosis were available it would be found to be almost universal. The highest incidence of the disease so far had been found in Holland France Malay States Sumatra and the Andaman Islands As far as was known at present the disease was absent from Egypt Arabia and Persia and evidence of it in India was scanty Possibly strong sunlight was an important factor for this was lethal to the organism In Great Britain the organism was first isolated in 1932 but very few records of its incidence were published until July 1934 when Fairley showed that the disease occurred comparatively frequently among sewer workers in London Since then 142 British cases had been authenticated There were no data in this country from which to estimate the proportion of jaundiced cases to the total number but in the British army in Flanders, Stokes and Ryle had reported that 60 per cent did not develop jaundice and Schuffner had found the same percentage in an epidemic in Holland Alston and Brown had found agglutinins and protective antibodies in the blood of 9 out of 45 London sewer workers who said they had never had jaundice and similar figures had been recorded among fish workers in Aberdeen It was probable therefore that the disease was much more prevalent than would be expected from present records There was no record of a second attack and agglutinins had been found in the blood twelve years after the first

The spread of Weil's disease was almost entirely due to rats and other rodents which harboured the organism in the kidney and excreted it for long periods without disturbance of their health. The proportion of infected rats was highest among the middle aged and less among the young and old and the only apparent result to the rat was the production of specific antibodies in the blood The leptospira had been found in rats in rural and urban districts in almost all parts of the world In this country the incidence of infection in the brown rat had been reported to be as high as 41 per cent The only mammals other than rodents which had clearly been shown to harbour the infection in overt and latent forms were the dog and, rarely the fox Dogs were therefore possible carriers but Dr Alston thought the risk would not be found to be as great as that from rats It was possible that pigs were sometimes infected as a butcher had been known to develop Weil s disease 8 days after killing a jaundiced pig Infection of one human being by another was very rare but Schuffner believed that a woman had been infected in coitus and Taylor and Goyle that in the Andaman Islands urination on the ground by men with slight infections had helped to spread the disease The organism was very precarious in its viability It was killed by salt water or an acid reaction the fact that infection tended to follow immersion in some only of the canals in Holland was attributed partly to their varying salinity Weil originally thought that infection entered through the alimentary tract but Inada came to suspect that it did so through abrasions in the skin This Dr Alston thought was borne out by the greater incidence among builders than flushers working in sewers Some cases had followed rat bites and others dog and ferret bites apparently by mechanical transmission as the dogs and ferrets had just bitten rats Infection was commoner amongst involuntary than among voluntary bathers in canals presumably because unpremeditated immersion often caused struggling and let water enter the respiratory tract Indisputable evidence of alimentary infection was rare Insects had not been known to transmit the disease The fatality rate had been considered to be high at a time when the mild and subclinical cases were not recognised but in the last 142 cases observed the death rate had been 15 per cent

The frequency of infection among men and women depended so much on exposure through their occupation that the influence of sex was obscured but among fish workers in Aberdeen the percentage infected was the same in both sexes The incubation time according to Schuffner varied from 4 to 19 days the majority of the cases occurring between the seventh and thirteenth The greater number of cases were associated with a few occupations which had rats, dampness, and abrasions in common, fish cleaners, coal miners, canal workers, gravel pit workers, bathers, and people living in rat-infested houses were those most liable to be affected in Great Britain The rat infestation of the fish cleaning shops was due to the fish remnants left lying at the end of the day and leptospira could be found in washings from the tables and floors, this lack of cleanliness was being tackled and prevention should be comparatively easy Dr Alston showed a slide of a fungus which only grows on rat fæces and which served as an indicator of rat infestation in sewers, the rats entered through imperfections in the drains, consequently care was being spent on mending the defects The relation of the *L icterohæmorrhagiæ* to other similar organisms had not been settled, in particular the question whether the non pathogenic organism *L biflexa* could become pathogenic remained open

DISCUSSION

The President mentioned Murgatroid's suggestion that the organism might occasionally establish itself in man and spread from man to man He asked whether it had been proved that any of the pathogenic species could be established as free living organisms

Dr H J Parish wondered why in a country with our large population and with such a large proportion of the rats infected there were not more cases of Weil's disease He also wondered why so many cases had been reported among those who fell into canals where presumably rat excreta were greatly diluted while relatively few occurred among fish workers The possibilities of active immunity were very interesting where other preventive measures were difficult, as for instance, among miners Should laboratory workers protect their eyes with goggles?

Dr J D Rolleston had read in the French literature of a special meningeal type affecting sewer workers and well sinkers He asked whether there were more severe and fatal cases in Japan

Dr T White had seen cases in the war and had considered that infection occurred through the alimentary tract after the rats had walked over the food

Mr Graham asked whether there was any real reason to think that the disease had been recently introduced into this country He had been connected with sewage work for 30 years and had only heard of the disease in the last three or four years He had always boasted before that sewage work was one of the healthiest occupations

Dr A Joe wanted to add brewery worker to Dr Alston's list of occupations

Dr Alison Glover asked how long the pyrexia lasted in the cases without jaundice and whether the black rat was as susceptible as the brown

Dr E W Goodall said it was odd that so many cases occurred among fish workers who were in contact with so much salt water, presumably the rats became infected elsewhere —In answer to his questions Dr Alston said that all but one of the cases among fish workers had occurred in Aberdeen, and that the leptospira only survived about 24 hours in sewer slime, only when the organism was constantly excreted in large quantities was there a risk of infection.

Dr Percy Stocks asked whether rat bite fever were sufficient title for the disease

REPLY

Major Brown, in reply, said that if the disease could not be called Weil's disease it should be called spirochætal jaundice, not infective jaundice which might cause confusion with infective catarrhal jaundice The organism could be carried by the rat but was not normally to be found in its mouth Brown rats were more susceptible than black He had had no experience in this country of cases without jaundice, but from the literature the degree of pyrexia seemed to be slightly less The sera of the meningeal forms was said to give a curious agglutinin reaction missing the one in ten dilution He thought that only chance prevented greater incidence the means of entry as well as the infective material had to be there There was no doubt that it was not a new disease, only four cases had been reported between 1922 and 1934 while 142 had been found in three subsequent years with better methods

MANCHESTER MEDICAL SOCIETY

At a meeting of this society on Feb 3rd a symposium on

Hæmorrhagic Diathesis

was opened by Dr J F Ward He said that although the term usually signifies the group of purpuras it was also applied to other conditions in which repeated hæmorrhages occur from capillaries, either spontaneously or as the result of minimal trauma, and included the hæmorrhagic disease of the new-born and hæmophilia These various conditions differed in respect of hereditary influences, the most frequent site of hæmorrhage, coagulation, and bleeding time, and number of platelets in the circulation Different figures given for coagulation time by different workers were due chiefly to lack of uniformity and a satisfactory method of estimation

Hæmorrhagic disease of the new-born was a deficiency disease, since it was satisfactorily treated by injections of whole blood, but the missing factor was not known In scurvy the hæmorrhagic tendency was clearly due to lack of vitamin C It was doubtful if true hæmophilia ever occurred in the female sex although cases were reported in which it seemed possibly to have occurred Foulis and Crawford's case was difficult to explain unless it were due to marriage of a hæmophilic with a female "carrier" Pseudo hæmophilia had several characters different from true hæmophilia and some of the reported cases were probably examples of inherited purpura No treatment was known that would cure hæmophilia, temporary arrest of hæmorrhage was satisfactorily obtained by blood transfusions, and in external hæmorrhage, by application of Russell's viper venom, which shortened the coagulation time and could be used in high dilution without diminishing its potency Timperley and Naish's treatment with egg white or mucic acid was on trial and has given promising results in their cases

Dr John F Wilkinson discussed the non familial hæmorrhagic states or purpuras After considering their main features, and classifying them into primary (idiopathic) and secondary purpuras, he dealt in detail with the primary purpuras, represented by Werlhof's purpura hæmorrhagica and by the Henoch Schonlein purpuric syndrome The features of purpura hæmorrhagica were, he said the occurrence of hæmorrhages or purpura in or from the skin or mucous membranes with a reduction in platelets, prolonged bleeding time, normal coagulation time, and non retractile blood clot The initial manifestation might be epistaxis hæmaturia hæmatemesis, melæna, or intracranial hæmorrhage Spontaneous remissions were common and there was a tendency to seasonal onset of symptoms Dr Wilkinson discussed the blood changes in this group of purpuras and indicated their importance in association with the clinical findings in making a diagnosis and deciding upon the correct lines of treatment He assessed the various forms of treatment and demonstrated the extreme value of splenectomy in association with blood transfusion with the aid of case records The *indications and contra indications* for splenectomy and the need for choosing the right moment for operation were then considered Dr Wilkinson said that as distinct from these purpuras, the group reported by the Henoch-Schönlein syndrome was less constant. This condition appeared to lie between the urticarias and the purpuras As a rule the blood findings were normal. Henoch's purpura and Schönlein's purpura were not distinct entities but merely varieties of the same syndrome Purpura was not the predominating symptom The condition was usually seen in girls and lasted throughout life with remissions and relapses but the symptoms might change in any person at different times the main ones being pyrexia pains in the joints gastro intestinal symptoms (nausea vomiting colic diarrhœa), blood and mucus in the stools, angio neurotic œdema, and so on Treatment was unsatisfactory Dr Wilkinson concluded with a discussion of the importance of vitamin C in relation to the purpuras

Dr WILLIAM BROCKBANK referred to two cases of purpura hæmorrhagica that had responded well to splenectomy and were well several years later —Dr C P LAPAGE said that he had had good results with potato cream in the treatment of infantile scurvy —*Dr W J S REID again emphasised the difficulties of* estimating accurately the bleeding and coagulation times and described a method he had employed with success; he also referred to a case of familial telangiectasis under his care

LIVERPOOL MEDICAL INSTITUTION

AT a pathological meeting of this institution on Feb 18th with Prof. R E KELLY the president in the chair a paper on the

Œstrin Content of Blood and Urine

was read by Dr O VAUGHAN JONES In the non pregnant woman he said the Graafian follicle was the chief producer of œstrin whereas in pregnancy the placenta was responsible for the vast quantities secreted During pregnancy the œstrin content of the blood rose continuously but the excretion of the hormone in the urine was complicated by the fact that about 90 per cent of it was excreted in the combined form After the third month there was a rise in the amounts of combined form excreted this rise being more conspicuous after the sixth month. The concentration of the free form of œstrin in the urine was low throughout pregnancy but shortly before parturition the amounts of the free form rapidly increased It was to be expected that any upset of the normal course of pregnancy would be shown by changes in the hormone balance in blood and urine and the quantities found should be a guide to the viability of the fœtus The Aschheim Zondek test was a test for the viability of the placenta, not of the fœtus When therefore the fœtus died in utero the Aschheim Zondek test could be and often was positive—this being probably due to the retention of some active chorion epithelium which maintained the production of prolan But it had now been generally agreed that the placenta produced œstrin as well as prolan On this assumption it seemed likely that the death of the fœtus which entailed the interruption of the placental circulation might have an influence upon the hormone level in the blood It had in fact been found that the blood œstrin fell to a low level when the fœtus died —

	No of cases	Blood œstrin.	Subsequent history
Normal pregnancy	25	Positive.	Pregnancy continued
? Missed abortion	1*	Negative.	Macerated fœtuses delivered
? Intra uterine death	29	23 negative. 6 positive.	Macerated fœtus Fœtus alive

Negative = less than one mouse unit in 40 c.cm blood.

Dr Vaughan Jones concluded that the blood-œstrin test was a valuable and reliable means of ascertaining the viability of the fœtus It was essential to discover the amount in the *blood* for the total œstrin in the *urine* of women carrying a dead fœtus did not differ much from that of normal pregnancy

ROYAL MEDICO-CHIRURGICAL SOCIETY OF GLASGOW

AT a meeting of this society held in the eye department of the Western Infirmary on Feb 10th with the president Mr G H EDINGTON in the chair a paper on

The Biomicroscopy of the Fundus Oculi

was read by Prof. A J BALLANTYNE. Ophthalmoscopy was he said essentially a branch of microscopy for with the ophthalmoscope they examined structures which were more or less transparent, under varying degrees of magnification, and with various forms of illumination. Since there were many fundus lesions which it was difficult or impossible to explain by histological methods it was all the more necessary that they should employ every refinement of ophthalmoscopy which made the ophthalmoscope a more perfect microscope. This purpose could be served in two ways—namely by focal illumination of the fundus and by the use of filtered or selected light In the anterior segment of the eye focal illumination was employed (1) by direct illumination (2) by lateral or proximal illumination (3) by retro illumination (4) by examination in the zone of specular reflection and (5) by examination in optical section. Within certain limits these methods all had their application in the examination of the fundus Modern interest in the examination of the fundus with selected or filtered light dated from Vogt's employment of an approximately red free light to demonstrate that the yellow spot was not merely a post mortem phenomenon but could be seen in the living eye In many other ways the fundus obtained with the red free light differed from that obtained with the mixed light of the electric bulb and for most purposes the light of the mercury vapour lamp was a good substitute An entirely different picture was obtained by the use of a sodium vapour lamp the bright monochromatic yellow light enhanced the definition of fundus details Clear definition was further assisted by the fact that the vessels stood out darkly against a pale background Surface reflexes were abolished and the retina rendered more transparent Hence deep seated lesions especially in the choroid were more easily seen The advantages both of focal illumination and of examination with selected light could be concluded be obtained without costly apparatus.

NEW INVENTIONS

A SIMPLE EXTENSION APPARATUS FOR FOREARM AND WRIST FRACTURES

In industrial centres such as Sheffield numerous fractures of the forearm and wrist are reduced daily Anybody who has had to assist and to pull steadily and repeatedly for five to ten minutes, will, I believe, appreciate that it is tiring and often painful work and will welcome a simple mechanical method

The apparatus shown in Fig 1 consists of a steel plate in which are drilled numerous holes Through these are passed two long screws with hooks at one end and butterfly nuts at the other The apparatus is fixed to the side of the fracture trolley by a strong thumb screw By reversal of the traction screws the apparatus may be used on either side of the trolley for either arm. The various positions of the holes are to allow reduction with the forearm in mid, supine, and pronated positions, according to the type of fracture The finger and thumb attachments consist of the raffia snares familiar to most people as Japanese toys, and now obtainable from Messrs Down Bros, Ltd. (22A, Cavendish square, London, W) These snares are slipped over the fingers and thumb and as a result of the method of plaiting, tighten and grip firmly when the distal ends are pulled To remove them, the extension is released and the two ends of each snare squeezed together in a longitudinal direction, when they slip off easily The snares are threaded through their ends with ordinary cord and are tied firmly to the traction rods by double knots The thumb is attached to one rod and the three fingers to the other, in fact, the apparatus replaces exactly the assistant's two hands. These snares are of standard size but in some cases are too small to fit over the thumb, Down Bros have therefore made a larger snare out of split bamboo The counter extension used is the webbing band attached to the wall described by Böhler[1] We have had no difficulty or complications using the snares, though in one case they were left on for twenty minutes

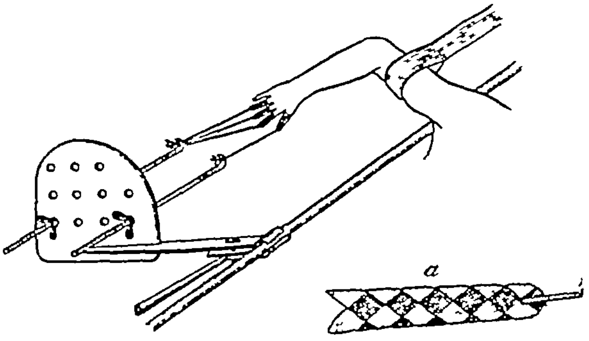

FIG 1 —The extension apparatus showing the method of application (a) a raffia finger snare.

Using this simple device, numerous cases of fore arm and wrist fractures, some with serious deformity, have been satisfactorily and easily reduced. In the fracture clinic now, we use the apparatus for fractures of both the forearm bones with any degree of angulation and shortening and also in fractures of the shaft of the ulna associated with dislocation of the head of the radius Colles's fractures are easily reduced with correct anatomical alignment By

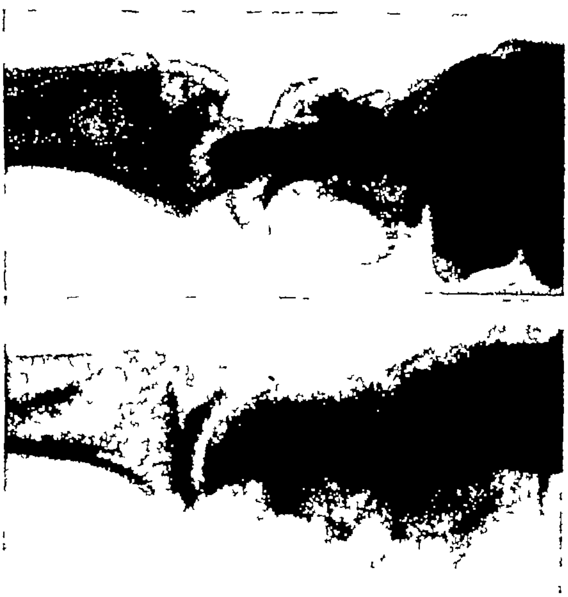

FIG 2 —Reduction of second degree perilunar carpal dislocation Above the separation achieved by extension in the apparatus Below after reduction

passing a wire extension through the thumb pulp, under local anæsthesia, and attaching it by a cord to a traction rod, Bennett's fracture dislocation of the first metacarpal is suitably extended while the plaster is being moulded correctly round the base of the thumb When the plaster has set, the extension wire is tied to a wire splint incorporated in the plaster, as described by Böhler, while the extension cord on the apparatus is cut and removed. Fig 2 shows the degree of extension attained in a case of second degree perilunar carpal dislocation which had occurred three days previously We had no need to resort to any violent manipulative methods If one accepts the statement that this type of injury is a result of a dislocation of the distal carpus around the semilunar bone then the obvious way to reduce it is first to separate the carpal bones by extension Replacement of the carpus is aided by pressing the distal carpal bones—chiefly the os magnum—ventrally and is achieved when the extension is released and the convexity of the os magnum is received into the concavity of the semilunar This is well shown in the radiograms Incidentally, the median nerve is in no danger from pressure if this method of reduction is used

Often while a steady pull—a thing so difficult to maintain manually for any length of time—is acting, one can apply a leg plaster to another case and so save not only energy but also time A further advantage is that the application of the plaster is made easier with the absence of the hands of the assistant, which, instead of being in the way, may be utilised by soaking and preparing the plaster slabs

The apparatus was made by a local blacksmith and has at least its simplicity and cheapness to recommend it

My thanks are due to Prof Ernest Finch, and to Mr F Holdsworth who is in charge of the fracture clinic of the Royal Infirmary, Sheffield, for permission to publish this article

RALPH SHACKMAN, M B Lond, F R C S Eng
Resident Surgical Officer to the Royal Infirmary, Sheffield

REVIEWS AND NOTICES OF BOOKS

Nostrums and Quackery

And Pseudo Medicine By ARTHUR J CRAMP M.D formerly Director of the Bureau of Investigation (1906–1936) Vol. III Chicago: Press of the American Medical Association. 1936 Pp 232

FOR nearly thirty years Dr Cramp directed a campaign to educate and enlighten the American public about pseudo medicine During the early years of his directorship he brought out two volumes of Nostrums and Quackery which had a wide circulation and influence The first volume, published in 1911 with a second edition in 1913 is now out of print The second volume published in 1921 and indexing the subject matter of both is still obtainable By 1930 sufficient material had been collected for a third volume which only now appears, some time after Dr Cramp's retirement owing to ill health. This volume differs from the others in being mainly a factual record, less space being given to the methods of the nostrum exploiter but there remains in the introduction and in the prefatory notes to the several chapters enough to give even the novice a fair outline of the exploitation of human credulity in the field of medicine

Dr Cramp points out that as far as the U S.A is concerned the pills and panaceas of to day cannot rightly be called *patent* medicines probably not half a dozen of them are really patented. The patent does not meet the vendor's need as it gives him a monopoly for only about seventeen years and publication of the composition would destroy the secrecy and mystery which are the foundation of his success. In confirmation of this Dr Cramp quotes this sentence of a letter from a drug journal to druggists

> It is practically impossible to prove that the therapeutic claims made for a preparation whose composition is not known, are false and fraudulent once however they are given the formulas, they can get as many doctors as is necessary to testify that the preparations made according thereto are not good for the diseases for which they are recommended

and the reply of an honest druggist to the effect

> "That you are afraid of revealing the nature of your preparations to your competitors is absurd There is no preparation on your list that cannot be matched or bettered by one in the National Formulary of the United States Pharmacopœia The sale of your preparations and of others like them depends on advertising and not on therapeutic value

The report makes joyful reading in places There is the story of "Professor Maurice Scholder who had obtained from a learned Dominican friar in Galicia a scientific secret that was the basis of his discovery for growing hair on bald heads He asked for specimens of hair to be sent to him and invariably reported that they were in a seriously undernourished condition. With Dr Cramp's help he reported in this sense not only on the fur of a platinum fox but on some filaments of twine stained black and brown by Dr Cramp himself More poignant is the evidence of a twilight zone in which it has too often proved difficult to distinguish between the quack with a scheme and the visionary with a theory

The book although dealing with conditions in the U S.A contains instruction of universal application and Dr Cramp may well rest content with the fruits of his life work

Malaria in Europe

An Ecological Study By L W HACKETT M.D D P H. Assistant Director International Health Division The Rockefeller Foundation London Humphrey Milford, Oxford University Press 1937 Pp 336 10*s* 6*d*

THE catastrophic results of malaria in Salonika during the war; its appearance as the most terrible epidemic of modern times in Central Russia and even in Archangel and the discovery of an epidemic of 5000 cases in Emden on the North German coast as well as of a few secondary cases in England, have drawn public attention to malaria in Europe From the studies of Swellengrebel in Holland, Martini in Germany and Central Europe Missiroli and Hackett in Italy Balfour Barber Rice and Shannon in Greece Collins in Bulgaria and Hill in Spain, there has emerged a uniformity of opinion on the control of malaria which does not entirely conform with the doctrines previously held by the so-called European school of malariology No better apostle of the new teaching gifted with a vivid style of expression could have been found than Dr Hackett whose style is vivid and whose information is up to date

The puzzling problems which European malaria presents such as anophelism without malaria has thrown new light on the ecology of this disease The epidemiology of malaria is by no means the simple problem that it was formerly thought to be it involves a study not only of man, but of his domestic animals in fact the whole of ecology No less than five biological races of the typical *Anopheles maculipennis* which have distinctive markings and breeding habits and which lay different patterns of eggs have been discovered. These bear the romantic names of *A typicus A messeæ A atroparvus A melanoon* and *A elutus* The knowledge gained of their habits and distribution is certainly applicable to other species of malaria-carrying anophelines in the tropics—as has already been found in the case of *A ludlowi* in the Andamans

A good deal of mystery and even romance is to be found in the story of malaria as already told and it looks as if there were much more to come Dr Hackett has provided a good introduction to this fascinating subject and has shown that Europe is likely to provide a signpost to the prophylaxis of what is popularly regarded as a tropical disease

Tissue Immunity

By REUBEN L KAHN M.S D.Sc. University of Michigan Ann Arbor London: Baillière Tindall and Cox 1936 Pp 707 34*s*

IT might be thought that our available knowledge of tissue immunity is so meagre that its description might be compressed into a few pages and the author who undertakes writing a book of 700 pages on the subject shows some temerity Dr Kahn's book is almost entirely devoted to descriptions of his own experiments Though much of the experimental work seems to have been carefully carried out it is not easy to see in what directions it has added to existing knowledge The central thesis of the book seems to be that reactions of hypersensitivity (allergic reactions) are an evolutionary by product of the mechanism of defence against parasitic invasion This is of course by no means a new conception and it has no very obvious advantages over the alternative view that the reaction to non living chemical agents is the more primitive Dr Kahn's book is not likely to be read by any but experts, and we doubt whether they will be impressed with the value of his experiments and views

Minor Surgery

Third edition By FREDERICK CHRISTOPHER, S B , M.D , F A C S , *Associate Professor of Surgery at the Northwestern University Medical School, Chicago* London W B Saunders Co , Ltd 1936 Pp 1030 42*s*

THE distinction between major and minor surgery is rather an artificial one, and it is obvious from the size of this work that Prof Christopher gives to the term " minor surgery " a wide meaning The book deals not merely with those minor operations which may be performed in a doctor's surgery or a hospital casualty department, but includes everything except the most formidable surgical procedures It should appeal to a large number of medical men the practitioner will find it a valuable guide to the minor operations which are within his scope, and the surgical specialist will be grateful for innumerable practical hints on technical detail. New sections in this edition deal with the healing of wounds, vascular surgery, new methods of treating fractures and sprains, and the pathology and treatment of lymphogranuloma inguinale and glomus tumours Many of the older sections have been considerably amplified The illustrations are skilfully chosen and reproduced The extensive bibliography of current literature is kept well up to date Prof Christopher evidently takes delight in discovering, trying, and making known to others the cunning little tricks which contribute to the success of any operation or contribute to the patient's comfort, and his colleagues have good reason to be grateful to him

Elementary Manual of Physiology

Fifth edition By R BURTON OPITZ, S M , M D , Ph D , Consulting Cardiologist, Lennox Hill Hospital , Consulting Physician, Cumberland Hospital, Brooklyn London W B Saunders Co , Ltd 1936 Pp 442 10*s* 6*d*

Human Physiology

Seventh edition By PERCY G STILES, Assistant Professor of Physiology in Harvard University Same publishers 1936 Pp 446 10*s*

THESE two books cover, between them, the field of elementary physiology Dr Burton Opitz has written a concise, business like account of " straight" physiology, of the type required by medical students , it is well illustrated and balanced, and would serve admirably for a first reading of the subject and as a text-book for nurses The author displays, if anything, too great an anxiety to be accurate as well as brief, and the style suffers in consequence , the book is like tapioca pudding—stodgy, but very safe and very nourishing Prof Stiles's work is, by comparison, effortless, and the reader is carried on smoothly and rapidly , from the literary point of view it is a better book. Its scope is, however, different, being more elementary, suitable for schools and the general reader It is not in any sense a popular treatise, but it presents physiology in relation to everyday life, and contains intelligent discussions of various points of hygiene and of questions like vivisection which certainly add to its value for the reader who may not be studying any other biological or medical subject

Management of Obstetric Difficulties

By PAUL TITUS, M.D , Obstetrician and Gynæcologist to the St Margaret Memorial Hospital, Pittsburg London Henry Kimpton 1937 Pp 879 36*s*

THIS book reflects the mature outlook of an experienced American obstetrician on his specialty His book has a wide scope, for the problems discussed range from those of conception to those of postnatal treatment As a whole the standard of the sections which make up the volume is high, and the importance of preventive medicine is stressed throughout The chapter on Cæsarean section is eminently sane and those on the incidental diseases of pregnancy are particularly good The bibliography is well arranged, with the prevalence of American and German authorities which characterises American work on medicine The sections which appear to us less satisfactory than the rest are those on the management of occipito posterior and breech deliveries The use of Willett's forceps is apparently gaining ground in America, but amniography and aspiration of the uterus in hydramnios are scarcely mentioned The illustrations are profuse and clear

British Journal of Children's Diseases

THE January–March issue contains a paper by Dr Alice Stewart entitled Gastric Acidity in Infants and Young Children Under Normal and Pathological Conditions, with Special Reference to Nutritional Anæmia The literature she finds shows (1) that there is no evidence of congenital achlorhydria, nor is it present in the healthy child , (2) that gastric acidity may be lowered by any parenteral infection, and especially in chronic gastro-intestinal disease , and (3) that the acidity is lower in infants than in older children Dr Stewart's own investigations were carried out on four groups of young children—(*a*) those with iron deficiency anæmia , (*b*) previously anæmic children, now in good health , (*c*) those with other illnesses , and (*d*) healthy children She believes that the deficiency anæmias of infancy are caused by pure iron deficiency, and that the impairment of gastric secretion found in the anæmic cases *is the result, not the cause of the* condition This low acidity, however, decreases still further the amount of available iron, thus aggravating the condition and preventing spontaneous cure —In a paper on Schüller-Christian disease, a triad of defects in bones, exophthalmus and diabetes insipidus, Dr F R B Atkinson has tabulated 103 cases in children up to the age of thirteen years inclusive, on 22 of whom autopsies were held A bibliography is appended —Dr R de Rohan Barondes of San Francisco contributes a paper on Apple Powder and its Application to Intestinal Disorders He maintains that apple powder may be substituted for and indeed is preferable to fresh apples in the treatment of acute and chronic intestinal diseases, since the powdered form enables it to be ready for use at all times Unlike fresh apple it can easily be mixed with milk without causing coagulation or curdling It does not undergo oxidation with the resulting brown colour as happens in apple pulp The powder acts quickly in controlling diarrhœas and dysenteries, and in producing normal stools No ill effects from its use are encountered.

The abstracts from current literature are devoted to tuberculosis

THE LANCET

LONDON SATURDAY MARCH 6 1937

SPECIFIC PROPHYLAXIS OF INFLUENZA

FOUR years ago it was shown that epidemic influenza is caused by a filtrable virus and ever since then the question has been—will this new knowledge lead to the discovery of a method of preventive inoculation? The only reasonable chance of controlling the disease lies in raising the immunity of the population and although the relatively short-lived immunity conferred by one attack does not augur well for any measure of specific prophylaxis the possession of accurate knowledge of the causation has raised fresh hope After all influenza has a definite seasonal incidence and its epidemics run a limited course of two or three months so that prophylactic inoculation conferring even a transient immunity might be far from valueless

Quite early in the investigations at the National Institute of Medical Research it was shown that the immunity conferred on the ferret by an attack of influenza though lasting but a few months could be restored when on the wane by a subcutaneous inoculation of virus[1] This route does not lead to infection in the normal animal and virus administered in this way stimulates afresh the production of neutralising antibody the titre of which falls with the return of susceptibility (It is noteworthy however that a ferret containing an appreciable quantity of neutralising antibody in its blood is susceptible to reinfection) In the past month three important papers on the specific prophylaxis of influenza have been published F M BURNET[2] reports some interesting observations on the infectivity of virus grown on the developing hen s egg for the ferret and mouse Previously he had shown[3] that serial passage of influenza virus on the chorio-allantoic membrane led to its becoming highly adapted to this medium so much so that it regularly invaded and killed the chick embryo in 48 hours He now finds that this egg passage virus when administered nasally to ferrets and mice causes no symptoms of infection in the large majority of animals and yet gives rise to a solid immunity Ferrets inoculated with egg virus do not give rise to contact infection and despite the possibility that the nasal instillation of such a strain of influenza virus in man on a large scale might occasionally produce epidemics BURNET thinks that this method is more likely to be of service in the prevention of influenza than the parenteral injection of living or dead virus That the danger of creating epidemics by the prophylactic use of living virus on a large scale in the field is a real one is shown by the experience of SHOPE[4] with swine-influenza He records epidemics in two herds of pigs which were apparently due to the prophylactic administration of living virus intramuscularly a procedure which had seemed free from risk under laboratory conditions Impressed by this danger C H ANDREWES and WILSON SMITH[5] have concentrated on finding an efficient method of immunisation with killed virus Their experiments on mice show that mouse lung virus inactivated by low concentrations of formalin and given intraperitoneally immunises mice almost as well as living virus similarly administered. With a view to using such a vaccine in man they attempted to free the virus of extraneous mouse protein. Although they accomplished this the purified virus when formolised proved a poor immunising agent even when formolisation preceded purification. However they carried out a preliminary experiment on human volunteers and showed that formolised mouse lung virus injected subcutaneously produced *an appreciable increase in neutralising* antibody which might be maintained for at least 2½ months From America comes a paper by FRANCIS and MAGILL.[6] These workers have made use of virus grown in a chick-embryo Tyrode medium under which conditions it maintains its power to infect ferrets and mice when given by the nasal route and immunises without infecting when inoculated intraperitoneally or subcutaneously They have administered this living culture virus subcutaneously or intradermally to a group of 23 volunteers This procedure was not attended by any unpleasant reactions and no evidence was obtained that living influenza virus introduced by these routes appeared in the nasopharynx Further the persons so treated developed a titre of neutralising antibody which paralleled that resulting from natural infection both as regards degree and duration.

Considerable progress has thus been made towards finding a safe and adequate method of immunising man against the virus of influenza It will be necessary however *to try these methods* in the field before any definite conclusion can be reached about their efficacy

BORSTAL TRAINING

THE last general inquiry into English prisons was conducted by a departmental committee *appointed in 1894* by Mr *ASQUITH* who was then Home Secretary One of the matters referred to this committee was the subject of prison labour and occupation and its deliberations found expression in the Prevention of Crime Act 1908 whereby the Borstal system was inaugurated for young offenders from 16 to 21 the upper age limit having since been extended to 23 years It was the segregation of these young persons that transformed the conception of prison labour to one of vocational training This training has now become the indispensable characteristic of Borstal detention, and serves, also, as a useful index to the happiness and progress of the boys, for, as Mr **Rodger** remarks in the report[1] before us, "a boy who is vocationally efficient tends not only to be vocationally contented, but also to be generally contented, and, conversely, a boy who is vocationally inefficient tends not only to be vocationally discontented, but also to be generally discontented" It was hardly to be expected that vocational inefficiency with its accompanying discontent would disappear at once from Borstal institutions Such inefficiency seems to have been caused less by the imperfect working conditions, which existed in some of them—out-of date equipment, undue pressure on production, and so on—than by the unsuitability of the workers themselves A really able boy frittered away his time doing work which provided him with little scope for his abilities, while good money was wasted in requiring another to attempt work for which he was not fitted Thus the procedure adopted in assigning boys to their various work-parties came under suspicion Nominally, this duty was performed by the house masters, in practice however the boys often made their own choice selecting occupations in which they were interested But inasmuch as interest is not the only determinant of occupational efficiency, failures were inevitable

[4] Shope R E (1936) *J exp Med* 64 47

[5] Andrewes C H and Smith W (193) *Brit J exp Path* 18 43

[6] Francis T, jr and Magill, T P (1937) *J exp Med* 65 251

At this point the National Institute of Industrial Psychology was asked to survey the situation, and a preliminary experiment was made at Feltham in 1926 "to discover to what extent, if any, the use of psychological tests, by simplifying the problem of allocating the most suitable to the various working parties, would make for contentment and stability in work among the boys and reduce the frequency of requests for a change of task." The prison commissioners reported that none of the lads who were selected for work parties, on the results of the tests, applied for transfer to another party Accordingly a more extensive experiment was arranged, the results of which are here set out[1] Four hundred boys, taken at random at Wormwood Scrubs from boys awaiting removal to Borstal, were examined before they began their training and vocational recommendations made These recommendations were forwarded to the institutions only in alternate cases, in the remainder they were recorded but not disclosed, the boys being allocated to their work-parties by their house masters as before Thus the relative merits of the old and new methods could be assessed with a fair degree of accuracy, half of the 400 boys forming a control group For various reasons, 82 of the boys examined dropped out of the experiment, but fortunately there remained an almost equal number in each group—158 boys in the "recommended" and 160 in the "control" group Of the former, 110 became Grade A workers, of the latter only 73, in other words, 69 5 per cent of the investigator's recommendations and only 45 6 per cent of the house masters' recommendations led to satisfactory results Mr Rodger points out that the difference is statistically significant, it is almost certainly not a chance difference The success of the new procedure was shown more clearly by some of the work-parties than by others, but in every party it was definite

Extracts from some of the tests used are included in an appendix to the report, they were applied to ascertain intelligence, the judgment of shapes and sizes and ability to reproduce them, mechanical ability and manual dexterity Mr Rodger lays stress on the study of temperament Whatever may be the value of carefully interpreted results of carefully constructed and carefully administered tests for general and specific abilities, these do not in themselves form an adequate basis for vocational guidance Ten temperamental characteristics were selected for study—sociability, affection, cheerfulness, assertiveness, anger, energy, carefulness, perseverance, ambition, and stability Such studies of temperament can only be effectively made by a resident trained official with ample opportunity for modifying his recommendations in accordance with the needs of the moment Since Mr Rodger's report was written the prison commissioners have arranged with the National Institute for instruction in the use of vocational tests to be given to Borstal house masters, and several of them have now received such training The result of this investigation should encourage those who believe that the study of temperament is a primary need in the treatment of young offenders It may have even wider value in the prevention of delinquency

MEDICINE STAMP DUTIES

The recommendations, which we print on a later page, of the Select Committee on Medicine Stamp Duties are along the lines foreshadowed in a leading article a few weeks ago[1] and the lines have been extended The legislation which was the subject of the inquiries goes back to the year 1783 when the Chancellor of the Exchequer of that time, regarding "quack medicines" as "very proper objects of taxation," included them in his budget At intervals during the succeeding twenty-nine years the original measure was overhauled, but since 1812 the only alterations which have been made in the law have been due to decisions of the courts and not of the House of Commons Case law has been superimposed upon statutes which may have been within the context of the time when they were enacted, with the result that the provisions of the Stamp Duty Acts to day are, in the words of a learned judge, a mass of confused obsolete verbiage The task of the Committee was a difficult one The case for complete abolition of the duties was presented with great zeal and thoroughness, but the Committee emerged from its ordeal with the conviction that the duties should apply to a wider field and bring in a much larger revenue It is true that the

[1] A Borstal Experiment in Vocational Guidance By Alec Rodger M A (of the staff of the National Institute of Industrial Psychology) Industrial Health Research Board Rep No 78 H M Stationery Office 1937 Pp 41 9d

[1] *Lancet* 1936 2 1527

Committee has conceded one point as is seen by the recommendation that the duty should be at the rate of twopence instead of threepence in the shilling and should be graduated less steeply. That, however, is cold comfort for a trade which may be called upon to contribute millions of pounds sterling to the Exchequer whereas in the last financial year it contributed less than £800 000. It is estimated by the Committee that the duties now proposed would yield £3 300 000 in a full year; this we still think is a conservative estimate.

It should not be overlooked that the "recommendations" are recommendations and nothing more. It is unlikely that the Committee really intends to tax medicines dispensed on doctors' prescriptions, yet as we read the report that would be one of the effects of the proposals. If the active principle is extracted from the list of proposed dutiable articles it will be seen that it is thus: "substances of any sort held out directly or indirectly for the treatment of any part of the human body or for the protection or maintenance of bodily health should be liable to duty." There can be little doubt that the courts would hold that medicines prescribed or dispensed by medical practitioners were at least "indirectly held out" as being for the treatment of some part of the human body or for the protection of health. Any clause in any Bill presented to Parliament which interprets this recommendation as applying to medicines dispensed on the prescription of registered medical practitioners will need careful scrutiny, for the Committee can hardly have intended to bring such medicines into the same category as lipstick and hair oil. Had the Committee included in the list of exemptions the additional item "all medicines &c. recommended, sold or prescribed by registered members of the medical profession" there would have been no doubt about its intentions.

The recommendations are of a sweeping character. They stop up the holes through which lawful evasion has been possible and sweep in everything which looks like a drug or smells like one. They seek to deprive pharmacists of a privilege which Sir JOHN CAVENDISH, the Chancellor of the Exchequer who first imposed the duties more than a hundred and fifty years ago, intended their ancestors to enjoy. Pharmacists will be on all fours with the sixpenny bazaars should Parliament follow the advice of a Committee which sees no reason why "the modern chemist should have a very valuable preference" in the sale of preparations which claim the "known admitted and approved remedy" exemption which has hitherto enabled them to sell unstamped certain types of preparations liable to duty if sold by ordinary shopkeepers. The Committee appears to think that pharmacists are well enough endowed with advantages and cites the Dangerous Drugs Act as one of them, but while leaving the Pharmaceutical Society free to present its views on the matter of the proposed deprivation of a privilege which has been theirs for a hundred and fifty years it may be doubted whether the pharmacists' obligations under the Dangerous Drugs Act could not be more justly described as a responsibility than an advantage. A note of bitterness against pharmacists seems to have found its way inadvertently into a rapidly prepared and on the whole excellent report. It is suggested that "the presence of a registered pharmacist on premises where there are large sales of ready packed medicines is an illusory safeguard for the purchaser"; the business of pharmacy is however under strict statutory control and constant inspection.

Despite defects almost inevitable in a report which has to be ready by a certain date the recommendations are in the interest of the public and that is the thing that matters. The proposal to tax medicines dispensed on prescriptions of medical practitioners will hardly go any further and it is at least arguable whether soap should be taxed. Although it was not within its terms of reference to consider the ethics of the secret medicine traffic, the Committee says that the "appeal to fear, which is the underlying motive of large numbers of advertisements, is psychologically harmful."

PROTAMINE ZINC INSULIN

IN our correspondence columns this week the four firms that manufacture insulin in this country announce that they are issuing a protamine zinc preparation. It is just over a year since we first drew attention to the success attained by Prof. H. C. HAGEDORN of Copenhagen in his attempt to devise an insulin compound that would be slowly absorbed and thus have a prolonged and constant action. The compound he devised was made by mixing insulin hydrochloride with a protamine derived from the sperm of the rainbow trout, and its merit was that its insolubility was greatest at pH 7·3—i.e., at about the reaction of normal plasma. Our readers will recall that last August IZOD BENNETT and MORTON GILL confirmed the great value of this slow acting insulin for diabetic children. And on Jan. 16th we reported a sectional meeting of the Royal Society of Medicine at which HAGEDORN himself spoke and others testified that compared with ordinary insulin the protamine preparation is capable of keeping patients in better health on a smaller total daily dose.

The addition of small quantities of zinc to protamine insulin delays its absorption yet further. Prof. HAGEDORN said that he prefers "for his own part" to use a zinc preparation only when the ordinary protamine insulin is unsatisfactory, but the amount of zinc added is so small as to be generally considered harmless, and evidently the British manufacturers are persuaded that the advantages of the addition outweigh the disadvantages. In their latest communication[1] RABINOWITCH and his colleagues at Montreal are able to demonstrate that the zinc product is more stable than the ordinary protamine insulin and shows no change after as long as six months. They point out, however, that it is a delicate substance and say that they have to warn their patients against shaking it unduly and against allowing it to be contaminated with the alcohol commonly used for sterilising syringes (Possibly the same caution applies to ordinary protamine insulin, and if so the irregularities often noticed in its effect may perhaps be attributable to contamination with alcohol, or to a change in hydrogen-ion concentration) In clinical use the Canadian workers were very pleased with protamine zinc insulin, for a single daily dose sufficed in almost every case, the risk of reactions was much less than with ordinary insulin, and although protamine zinc insulin rapidly reduced the blood sugar level in hyperglycæmia, there was safety in its use because the fall was no greater with 100 units than with 50 It has been found advisable to bring the patients into hospital to " stabilise " them, and it is worth noting that stability is almost always achieved more quickly with " ladder " diets than by giving the full theoretical basal diet at once It is unnecessary, they find, to make very frequent blood-sugar determinations, and they rightly remark that the simpler the treatment the more likely the patient is to coöperate in it In 132 cases in which zinc protamine insulin was used there were 8 failures—i e , cases in which glycosuria could not be controlled, or the blood sugar could not be normalised in the fasting state, on a single dose daily Of these 8 cases, 3 could not be properly controlled even with frequent injections of ordinary insulin, while 3 others responded satisfactorily to two daily injections of the protamine zinc

[1] Rabinowitch, I. M., Fowler, A. F., and Corcoran, A. C.: Canad. med. Ass. J. February 1937, p. 111.

In the paper already mentioned IZOD BENNETT and MORTON GILL called attention to the difficulties and dangers attendant on the standardisation of these new products An international unit of insulin is a measure of the activity of a substance of which a standard sample is kept at the National Institute of Medical Research , but the activity of protamine insulin and of protamine zinc insulin differ somewhat from this and from each other, and it is hard to make comparisons Apart from this, the slowness, and occasional irregularity, with which the new products are absorbed often means that it takes a longish time to find the right dosage for a particular patient While it is true that the intensity of hypoglycæmic reactions is usually much diminished when the slower insulins are employed, it is also true that such effects may last longer Again it is to be remembered that owing to their slowness the new products are less rapidly effective in cases of diabetic coma, and most authorities agree that the old insulin should always be preferred for this most dangerous complication At a time when many a patient will be asking his doctor to apply the newest discovery it should be remembered that its use carries certain difficulties and that there are some cases in which the original form of insulin is both easier to use and more effective Prof HAGEDORN in his address quoted and amplified a saying of JOSLIN to the effect that the patient with diabetes is sailing on an uncharted sea and that on this dangerous voyage he is alone save for the company of his physician

ANNOTATIONS

EXPLOSIONS IN OPERATING THEATRES

MOST of the investigations which have been recently undertaken to ascertain the causes of explosion associated with the use of anæsthetics have been directed to discovering the origin of the heat or spark which starts the explosion The position in this respect has been made clear, and was expounded recently by Mr E H Rayner, Sc D , of the National Physical Laboratory, who did much of the necessary work.[1] He showed among other things that static electricity was unlikely to be a danger as long as the atmosphere of the theatre had a relative humidity of at least 65 per cent , which is usually the case in this country An investigation undertaken by Mr J H Coste for the London County Council dealt with the chemical side of the explosion problem. It will be remembered that the late Prof H B Dixon carried out a number of experiments for the Anæsthetics Committee on the ignition points of gases[2] He showed for example at how low a temperature mixtures of ether and oxygen might explode, and he drew special attention to the unrecognised explosibility of mixtures in which air was replaced by nitrous oxide in conjunction with ether or other inflammable gases The work of Mr Coste and his colleague, Dr C A Chaplin, confirms in several directions the previous conclusions of Dixon and his co workers, and defines the limits of explosibility of ethyl chloride vapour and air at roughly between 5 and 15 per cent Their examination of the atmosphere of theatres during open employment of ether, which included determinations of the percentages of ether vapour within a few inches of the patient's mouth and at various heights from the floor, corroborates the usual opinion that the danger of explosion or burning is very slight owing to the rapid descent of ether vapour through air Experiments in a large cylindrical vessel in which ether was spilt on to an absorbent surface at the bottom showed that the diffusion upwards of ether vapour is very slow compared with the horizontal spread, a conclusion which was confirmed by upsetting a bottle of ether on the floor of an operating theatre and examining the air above the spreading liquid Naturally there will be trouble if the heat—cautery, open flame, &c —is applied close to the source of the ether vapour but in ordinary circumstances, if the possible source of ignition is a foot or more above floor level, safety is assured Clinical experience upholds this finding It may be taken that, except in the immediate neighbourhood of the mask, the air in a theatre where ether is being freely used by an open method is not inflammable or explosive—however objectionable it may be otherwise

EFFECT OF POSTURE ON THE ELECTROCARDIOGRAM

CERTAIN persons of asthenic build show circulatory changes of unusual kind when they rise from the lying to the sitting or standing posture " Postural hypotension " is a condition on which much has now been written , but besides the blood pressure the pulse rate may also be affected, and at the same time, as described by Akesson,[1] important changes may appear in the electrocardiogram He investi

---

[1] *Lancet* 1936 2 1408

[2] *Ibid* 1927 2 247

[1] Akesson S (1936) *Uppsala LäkForen Förh* 42 263

gated ten patients with arterial orthostatic anæmia and found that as they passed from the lying to the sitting and then to the standing position there was with one or two exceptions, an increase in the pulse of 30 or more beats per minute and in the electrocardiogram a depression of the RS–T segment in leads II and III with a decrease in amplitude or actual inversion of the T wave in these leads In the lying position the curves were normal in all cases. These temporary changes in the tracing are similar to what may be observed as persistent abnormalities in organic myocardial lesions and it is held that in the cases studied an imperfect circulatory adjustment to posture leads to a diminished venous return to the heart, and a myocardial anoxæmia. The oxygen lack causes functional disturbance of the heart muscle, and this is expressed in the electrocardiogram Similar temporary changes in the tracing may be observed during an attack of effort angina, though here it is usual to find an abnormal curve apart from an attack. Since electrocardiographic changes which are dependent entirely on posture may be misinterpreted and accepted as evidence of an organic myocardial lesion Akesson recommends that tracings should be taken with the patient lying down

CAN IMPACTION OF THE THIRD MOLAR BE PREDICTED?

THE third molar and the complications which may arise from its impaction and consequent inability to erupt properly has been subjected to close study during the last few years by Mr Bowdler Henry[1] Not only has he ransacked the available literature but he has taken a large number of radiograms of students and others and has examined them with great care. It is not generally realised how serious may be the consequences of impaction of this tooth out of 622 cases collected by Mr Henry 42 ended fatally But quite apart from the possible danger to life the condition of impaction gives rise to much pain often if indirectly to suppuration while its removal is difficult and the after-effects are usually unpleasant. It is generally agreed that an impacted wisdom tooth is better removed while the surrounding tissues are healthy and that the post-operative sequelæ are less in young subjects Mr Henry in conjunction with Dr C M Morant has now carried out a statistical study of the four series of radiograms of medical and dental students previously collected[2] with a view to ascertaining whether there is any way of predicting ultimate impaction of the lower third molar The method used was to trace the outlines of the three molars and their pulp cavities and certain margins of the mandibles directly from the films These were enlarged by photography and from them a series of measurements were obtained and treated by statistical means The films used were all taken by the same extra-oral method and the main series consisted of 187 films relating to 127 persons ranging from 17 to 42 years Of the measurements taken some were discarded as being too liable to error; finally one index which the authors term the Third Molar Space Index was obtained which promised to give information as to the possibility of impaction This index expresses the maximum breadth of the outline of the third molar as a percentage of the space between the second molar and the border of the ramus It decreases with age and makes a clear distinction between cases of normal eruption and impaction for individuals aged 22 and over It was found that the values of this index ranged from 43 to 90 in individuals with normal eruption of the third molar In cases of coronoid impaction the range was from 90 to 142 while in mesio-oblique impaction the index varied from 81 to 160 Thus the higher the index the greater is the degree of impaction and hence the more reason for intervention. For example, if the index for an individual of 22 years is 120 or greater it should be taken as an indication for removal of the third molars The index would possess considerable value if its measurement in immature persons could be used to predict impaction at a later age At present the material available is insufficient for this purpose though the authors hold out hopes that if a larger amount of data were collected prophecy of this order might become possible a series of radiograms of 100 persons of each sex taken at yearly intervals from 16 to 22 years would be required. Investigations of this kind are of course laborious and expensive and the wastage from persons dropping out of the groups may lead to an annoying and progressive loss of data But this preliminary investigation opens up such interesting possibilities that we hope it may be found possible to extend it in the direction suggested.

CONSERVATIVE TREATMENT OF ACUTE INFECTIONS

SIR David Wilkie's contribution to a series of Clinical Recollections and Reflections appearing in the *Edinburgh Medical Journal* is devoted to the treatment of acute infections[1] There has lately been a fundamental change in outlook on this subject and he attributes it to the surgeon being trained to think more on biological and less on mechanical lines It must now be recognised he says, that in cases of infective punctured wounds of the hand with lymphangitis incision within 48 hours is a grave mistake. Bier's passive congestive treatment which consists in applying a special thin elastic bandage for 22 out of the 24 hours just firmly enough to produce a slight œdema but not duskiness relieves the pain and helps the condition to localise Failure to apply this treatment is tantamount to criminal neglect Hot fomentations and streptococcal antitoxic serum possibly supplemented by Prontosil, are used while the knife lies idly by For a simple boil the treatment recommended is complete immobilisation by strapping until the core is ready to separate Incision is wrong in theory because a boil is not an abscess and it is mischievous in practice What is good for a boil is equally good for a carbuncle; in severe toxic cases staphylococcal antitoxic serum is advised Turning to acute pleural effusions, Sir David points out that repeated aspiration is often necessary before localisation takes place For acute peritonitis return to the old physician's ways of heat and morphia with passive immunity by sera and fluid replacement if there has been vomiting gives the patient a better chance than immediate operation with multiple drainage and attempts at stimulating prematurely the adynamic gut with pituitary extract and the like. Perhaps of the several instances chosen in this paper none is more remarkable than the change of outlook in the management of acute osteomyelitis Dr Broadbent may be right when he says on p 564 of our present issue that this condition is a surgical emergency but if so the operation may certainly be a much more conservative one than has been generally held As Sir David Wilkie says, to day more and more osteomyelitis is treated by moderately free opening of the bone, packing with sterile vaselined gauze, and the enclosure of the whole limb in a plaster case for 3–6 weeks Under this treatment it is usual for pain and pyrexia to subside, and when the wound is dressed at the end of, say, a month, healthy granulation tissue covers its surface

SUBACUTE COMBINED DEGENERATION OF THE SPINAL CORD

It is generally accepted that liver preparations are efficacious in the treatment of the nervous lesions associated with Addisonian pernicious anæmia provided the total red cell count can be kept above 5,000,000 per c mm Hyland and Farquharson,[1] who analyse 74 consecutive cases, conclude that intravenous liver therapy is the method of choice and that a dose at least twice as great as that required to improve the blood picture should be given The best results were obtained when the patient was kept at rest in bed during the early months of treatment In all cases relief from symptoms was striking and often the authors noted definite improvement in objective neurological signs the most gratifying change was in the legs, depending on improvement in power, postural sense, and muscle tone, but there was also considerable recovery of sphincter control and of sensation The most persistent abnormal signs were the altered reflexes, but motor and sensory function commonly improved greatly in the absence of recovery in reflexes An analysis of the sensory changes showed a tendency to a segmental distribution which, Hyland and Farquharson suggest, indicates an origin in the spinal cord rather than in peripheral neuritis They believe that their evidence proves that much clinical improvement can occur even when the tracts of the cord are severely damaged. This improvement they attribute primarily to the subsidence of swelling associated with an active degenerative process, thus allowing undegenerated fibres to resume function and mildly damaged fibres to recover They do not think that peripheral neuritis plays any great part in the neurological manifestations of pernicious anæmia —a point of view at variance with that of many other workers Improvement in sphincter control and reflexes shows, in their opinion, that changes for the better may take place within the cord, while the segmental distribution of sensory lesions they regard also as evidence of central rather than peripheral origin

BACTERIA CHASED INTO BLOOD CULTURES

An interesting aid to the bacteriological diagnosis of typhoid fever is described in the *Presse Médicale* of Feb 3rd by Irdelp, Guchan, and Ugan of Istanbul. They investigated the effect of administration of adrenaline on the blood culture in typhoid fever, and they found that injections given just before the taking of blood may considerably enhance the chance of obtaining a growth of organisms The idea is that adrenaline causes the spleen to contract, and thus, to use the authors' expression, "chasser le microorganisme dans le courant sanguin" The actual procedure is to give an injection of 1 mg of adrenaline hydrochloride and to take the blood for culture 15–20 minutes later This interval was chosen on the basis of X ray examinations of the splenic contractions after the administration of adrenaline The method was tested on 103 blood cultures taken from 49 cases of typhoid fever, and the following Table gives the results of blood cultures taken before and after the administration of adrenaline

Day of illness	Blood culture				Percentage positives	
	Before injec		After injec		Before injec	After injec
	+	−	+	−		
7–14	23	11	26	8	67 6	73·6
15–21	14	28	25	17	33 3	59 5
22–28	0	27	0	27	0	0

It will be seen that it is especially in the third week of the disease, when positive cultures are usually difficult to obtain, that the adrenaline treatment seems advantageous It is stated that the typhoid patients suffered no kind of harm from the use of adrenaline for this purpose

PNEUMATIC TRANSFERENCE OF RADIUM

The use of large radium units has, in the past, been limited by the difficulty of providing adequate protection for staff and patients, and the method of pneumatic transference which allows the radium to be lodged in a safe during all manipulations is an important advance The apparatus is described in a recent article[1] by Mr L G Grimmett, physicist to the Radium Beam Therapy Research at the Radium Institute, London. Pneumatic transference was suggested for the Westminster Hospital unit in 1934, but not then fully worked out For the last two years however Dr Sievert[2] has had a five gramme unit working on this principle at Radiumhemmet, Stockholm The unit at the Radium Institute is mounted on ball bearings in a trunnion and counter balanced Gear wheels are provided for raising and lowering the apparatus, for rotating the trunnion about the vertical shaft, and for rotating the unit about its axis in the trunnion The radium is in special monel metal tubes, each containing 200 mg of radium element in the form of sulphate, and these are packed inside a steel bobbin. This bobbin is blown by air pressure from the safe through a flexible pipe which enters the unit along its axis of rotation in the trunnion It then passes through an internal pipe in the nozzle where it closes an electric contact and this registers its position by lighting a lamp in the operator's room There are three such lamps which show whether the radium is in safe, pipe, or unit The construction of the bobbin is very important It must be light and yet provide a sufficient surface against which the air pressure acts An arrangement of springs in the shape of hardened steel wedges brings the bobbin firmly into position and an ingenious arrangement compresses the air in front of it as it approaches its final position in the unit so that it acts as a resilient cushion The protection aimed at is 10 cm of lead, and this has been achieved except for the region immediately under the radium To increase the protection here as far as possible an eccentric lead screen is fitted which can be rotated so that the thickest portion lies between the patient and the radium For protection use has been made of the tungsten alloy described by

McLennan and Smithells This alloy has a density of from 16 to 16 5 g per c.cm and is roughly one and a half times as effective as lead. Different nozzles can be fitted to allow of treatment at varying distances and areas and a hand loading system is available in case of breakdown The air pressure is supplied by an ordinary vacuum cleaner Together with the lamp on the indicator board there is an electric clock which times the dosage it is started by the contact of the bobbin and runs only when the radium is in position Accurate localisation of the beam is facilitated by a directional calliper devised by Mr T A. Green F R C S The performance of the unit has proved satisfactory and other large units are likely to be installed on this principle in the near future.

NON RHEUMATIC CHOREA

It is generally assumed in the English speaking countries that chorea is almost always evidence of rheumatic activity This opinion is less rigidly held in many continental centres and of late years it has been suggested that chorea is sometimes wholly unrelated to juvenile rheumatism Coburn and Moore now report [1] that in a group of 114 patients attending monthly at a rheumatic clinic for periods of 2–10 years, there were 34 (approximately 30 per cent) who developed no signs of rheumatism apart from repeated chorea In another group of 137 consecutive admissions to a New York hospital for chorea 69 had no history or stigmata of rheumatic disease and though the other 68 had shown rheumatic manifestations in 20 of them attacks occurred when the rheumatism appeared quiescent The choreic child may have no family history of rheumatism and may never show any signs of the disease he may have chorea repeatedly without any preliminary infection of the respiratory tract and without any change in blood sedimentation rate or leucocyte count Other observers have pointed out that the sedimentation rate in uncomplicated chorea is usually normal and this according to Coburn and Moore is strong evidence against the rheumatic origin of chorea. They conclude that the physiological background necessary for the development of chorea may be prepared by a number of abnormal conditions but is especially well prepared by the rheumatism—which accounts for the frequency of chorea in rheumatic subjects On the other hand the factor that initiates the attack of chorea may be entirely independent of rheumatic activity and is probably often psychic It is relevant to note that Dr Lindesay Neustatter [2] working at Guy's Hospital has come to the conclusion that there is probably a common diathesis for nervousness and rheumatism And he thinks that chorea occurs in children who are constitutionally nervous.

STUDIES ON CHRONIC ARTHRITIS

While we have now fairly full knowledge of the anatomical changes in the joints themselves in chronic arthritis we have hardly an inkling as to either their immediate or their remote causation Even our descriptive knowledge of the subject is in a backward state and there is still a wide field of study open to the clinician who has the patience and tenacity to undertake the study of this disabling chronic disease There is much in the saying that to know the natural history of disease is to know more than half medicine It is in particular precise knowledge of the premonitory and incipient signs of chronic arthritis that is needed Until these can be separated from the trivial rheumatic troubles of common life it is difficult to devise any scheme of prevention or early treatment It is at the early stage too that a search for the possible infecting agent should hold most promise A valuable study of spondylitis by Dr Gilbert Scott [1] illustrates the kind of reconnaissance which must take place in the campaign against rheumatism before the sober work of advance and consolidation can proceed He recognises two main types spondylitis osteo arthritica and spondylitis adolescens, the latter being always associated with X ray changes in the sacro iliac joints while in the former the sacro iliac joints are normal. The changes in the sacro iliac joints in spondylitis adolescens may precede the more obvious signs of spondylitis by many years and may be unaccompanied by local pain in the sacro iliac joints A prespondylitic syndrome can however often be recognised consisting in recurrent attacks of rheumatic pain in the limbs thorax abdomen and so forth In such cases an X ray examination of the sacro-iliac joints may be of great value in diagnosing the condition at an early stage *the more so* as according to Dr Scott good therapeutic results may be obtained with X rays if treatment is initiated during the incipient stages

Other articles in this volume are by Dr H Warren Crowe on the pathogen selective culture method and its bearing on chronic rheumatic disease and by Dr Harry Coke on the differential sedimentation test Dr Crowe by no means accepts the Solis Cohen pathogen selective test as a final method of tracing an infection to its focus but he has faith in the value of the test in the study of chronic arthritis The organisms appearing in positive tests were mostly enterococci (including *Str zymogenes*) *hæmolytic streptococci* and staphylococci of a certain type (called by Dr Crowe *Staph flavus*) In a large number of cases of chronic arthritis investigated the highest percentage of pathogen-selective positive sera were met with in the groups commonly regarded as infective in origin—e g rheumatoid arthritis—but in no group was the percentage so low as to suggest the existence of an entirely non infective group The rather complicated test described by Dr Coke is based on the interaction of the positively charged serum proteins in acid medium with negatively charged ortho vanadic acid The final readings are made with a refractometer According to its author it gives more valuable clinical indications than the usual blood-cell sedimentation test and has the added advantage that the patient need not personally attend the laboratory

FREEDOM FOR RESEARCH

The obliquity of antivivisection propaganda is once more illustrated by two Bills before the House of Commons. These are the Vivisection of Dogs (Scotland) Bill and the Cinematograph Films (Animals) Bill a private members Bill sponsored by Sir Robert Gower The danger attending such attempts to hamper medical investigation is that whereas officials of the antivivisection societies spend lavishly their own time and their subscribers money in support of them research workers and organisations can only devote spare moments surplus energy and slender resources to countering what they regard as spiteful and nonsensical propa ganda, and unless vigilance is displayed a damaging Bill may one day slip through Parliament Unfortunately a few of those who allow their names to be used as supporters of the antivivisection movements are medical men The fact that, often long ago, they passed certain examinations does not as a matter of course given them the right to be heard when they deny the importance of the results obtained by other members of the profession from animal experiments, but it weighs to some extent with a section of the public already prejudiced against such experiments The utterances of distinguished investigators whose attention has been especially focused on the importance of experiment on the human subject have, moreover, been twisted and used to obscure the issue, especially as regards the use of dogs for experiments The whole question has been investigated by impartial inquirers over and over again and always with the same result as was reached by the Royal Commission of 1912—namely, that "experiments upon animals, adequately safeguarded by law, faithfully administered, are morally justifiable and should not be prohibited by legislation," and the question of whether the dog should be used in a particular case is one for experts As regards experiments on the cardiovascular system, for example, Sir Thomas Lewis has pointed out that the circulation of dogs more closely resembles the circulation of man than does that of any other domesticated animal, and that information derived from experiment upon unconscious dogs is being constantly used in the practitioner's daily work. The meaning of such common symptoms as palpitation, breathlessness, giddiness, fainting, and innumerable other forms of distress have been elucidated in this way and the technique of any number of therapeutic measures in routine use—e g, blood transfusion, or rectal feeding—is based on knowledge won by animal experimentation

[1] Charterhouse Rheumatic Clinic Original Papers London Humphrey Milford, Oxford University Press 1937 Pp 3 15s

Even more insidious than the Bill designed to prevent the vivisection of dogs in Scotland is the Cinematograph Films (Animals) Bill, which proposes to prohibit the production or exhibition of (*a*) any film, the producing or making of which involves suffering to animals, or (*b*) any film depicting or purporting to depict combats with or between animals, or the suffering, terror, or rage of animals, and provides that "in any proceedings brought under this Act the court may, until the contrary is proved, infer from the incidents depicted or purporting to be depicted by the film that suffering to animals was involved in the producing or making thereof" Certain objects of the Bill may be excellent but the deliberate omission of any exemption under the Act 39 & 40, Vict cap 77 would mean that the present practice of preparing films showing experiments on animals for teaching purposes or for showing the results of research would have to be discontinued The consequence of such a provision would be an increase of experiments under Certificate C

In antivivisection propaganda misleading statements are constantly being made The central fact that operational experiments are only performed under deep anæsthesia and with the strictest precautions to avoid suffering is not allowed to emerge, the advantages which have accrued from experiments on dogs are concealed and groundless distress is given to many right minded men and women by suggestions of cruelty, sometimes pictorial where none actually exists Doctors could help, probably more than any other body, in creating an informed and intelligent public opinion If they do not know enough of the facts these can be obtained from the literature issued by the Research Defence Society (11, Chandos-street, W) or from a well balanced memorandum upon the Dogs Protection Bill by the Medical Research Council (1927, H M Stationery Office, 2*d*) The closing paragraph of this memorandum supplies a cogent answer to some of the charges which are brought, and raises a useful issue for future legislation Many members of Parliament, and particularly the medical members of both Houses, have in the past helped to protect scientific workers from the consequences of unjust or pernicious legislation, and we have confidence that now and in the future their good offices will be exercised again and again as need arises

---

ON March 9th and 11th Dr Crighton Bramwell will deliver the Lumleian lectures to the Royal College of Physicians of London He will speak on the arterial pulse in health and disease The lectures will be held at 5 P.M and members of the medical profession will be admitted on presentation of their card.

THE Royal Society of Medicine will hold a reception on the evening of May 10th to celebrate Coronation Week. Medical visitors to London from the Empire overseas will be welcome to attend this reception, but as accommodation is limited those who wish to take advantage of the invitation are asked to communicate with the secretary of the society at 1, Wimpole street, London, W 1, not later than May 1st

THE fourth Biennial Informal Conference of the British Empire Cancer Campaign will be held on Tuesday and Wednesday, March 16th and 17th, at the Royal Society of Medicine, 1, Wimpole street London, W Admission to the conference will be by card only and applications should be made to Mr Lawrence Abel or Dr R W Scarff, the joint secretaries of the Organising Committee of the Campaign (12, Grosvenor crescent, London, S W 1) There is also to be a dinner on Wednesday, March 17th, at the Langham Hotel Intention to be present should be signified to the joint honorary secretaries, and the dinner will be an informal one in respect of dress

---

AN INSTITUTE OF SANITARY SCIENCE —A meeting was held in Dublin on Feb 26th to form an Institute of Sanitary Science Mr Nicholas O'Dwyer, who presided, stated that among the objects of the institute would be training for minor public health work, and the holding of examinations and issuing of certificates for proficiency, the conferring of fellowships, memberships and associate memberships, the maintenance of a museum library, laboratory, and lecture chamber, and coöperation with other bodies interested in the promotion of sanitary science A committee was appointed consisting of members of the medical engineering, and nursing professions

FEDERATION OF THE HEALTH RESORTS OF FRANCE An Easter tour under the management of the Federation is planned, the itinerary in the Riviera comprising Cannes, Grasse, Nice Menton and Monaco, the tour will take place from March 21st to 28th, and for medical men and their families the inclusive charge of Frs 1000 will be made plus a small booking fee The tour is under the direct organisation of the Société Médicale de Climatologie et d'Hygiène du Littoral Méditerranéen, and a reduction of 40 per cent is granted in respect of French railway fares

During the same period a congress on pediatrics under the presidency of Prof Nobecourt, will be held Applications for further information should be made to the Federation of the Health Resorts of France Tavistock House Tavistock square, London, W C 1

PRINCIPLES OF MEDICAL STATISTICS

X—THE COEFFICIENT OF CORRELATION

A PROBLEM with which the statistician is frequently faced is the measurement of the *degree* of relationship between two or more characteristics of a population For instance in a particular area the air temperature is recorded at certain times and the mean air temperature of each week is computed the number of deaths registered as due to bronchitis and pneumonia is put alongside it Suppose the following results are reached :—

Mean temperature of week in F	Number of weeks with given mean temperature.	Mean number of deaths registered as due to bronchitis and pneumonia in these weeks.	Range in weekly deaths.
35–	5	253	180– 84
38–	7	205	147–238
41–	10	130	94–180
44–47	4	87	60–112

There is clearly some relationship between these two measurements As the mean weekly temperature rises there is a decrease in the average weekly number of deaths from bronchitis and pneumonia, which fall from an average of 253 in the 5 coldest weeks to an average of 87 in the 4 warmest weeks On the other hand there is at the same mean temperature a considerable variability in the number of deaths registered in each week as shown in the ranges given in the right-hand column In individual weeks there were sometimes for instance more deaths registered when the temperature was 38°–41° than when it was 35°–38 In measuring the closeness of the relationship between temperature and registered deaths this variability must be taken into account

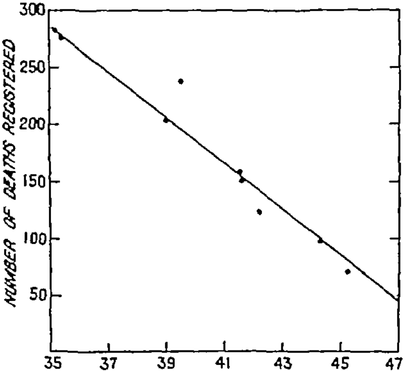

FIG 6.—Number of deaths registered in each week with varying mean temperatures A scatter diagram

The declining number of deaths as the mean temperature rises, and also the variability of this number in weeks of about the same temperature are shown clearly in Fig 6—known as a *scatter diagram* It appears from the distribution of the points (each of which represents the mean temperature of and the deaths registered in one week) that the relationship between the temperature and the deaths could be reasonably described by a straight line such as the line drawn through them on the diagram The points are widely scattered round the line in this instance but their downward trend follows the line and shows no tendency to be curved The means in the table above very nearly fall on the line In such instances a satisfactory measure of the degree of relationship between the two characteristics is the coefficient of correlation the advantage of which is that it gives in a single figure an assessment of the degree of the relationship which is more vaguely shown in the table and diagram (both of which are however perfectly valid and valuable ways of showing associations)

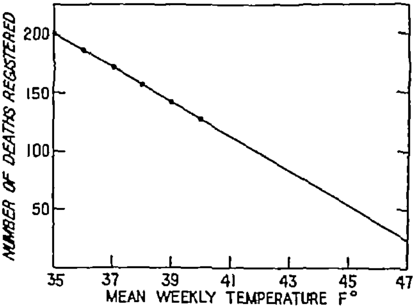

FIG 7.—Number of deaths registered in each week with varying mean temperatures Hypothetical case of complete correlation.

Dependent and Independent Characteristics

There are various ways of considering this coefficient. The following is perhaps the simplest

(i) Let us suppose first that deaths from pneum[illegible] and bronchitis are dependent upon the temperat[illegible] of the week and upon no other factor and also f[illegible] a straight line relationship—i e for each tem[illegible] there can be only one total for the death [illegible] total falls by the same amount as the te[illegible] increases each further degree Then our sca[illegible] gram reduces to a series of points lying [illegible] a straight line For instance in Fig [illegible] total 200 at 35° 185 at 36 170 at [illegible] weekly temperature there is only [illegible] the deaths the number of which [illegible] temperature rises one degree [illegible] temperature we can state pr[illegible] of deaths No error can be ma[illegible] round the line

(ii) Now let us suppose th[illegible] completely independent of the [illegible] fluctuate from week to week for [illegible] When the temperature is low [illegible] no reason why we should observe a [illegible] of deaths than when the tem[illegible] or vice versa If we had a very la[illegible] records we should observe at ea[illegible] kind of total of deaths The [illegible] take the f[illegible] shown in Fig 8 [illegible] in p[illegible] At 35 there were [illegible] weeks in wh[illegible] recorded [illegible] 175 and [illegible] at 36° [illegible] and similarly [illegible] higher temperature The average of the weekly totals of deaths observed is the same at each temperature and is equal to the average of all the weekly observations put together, for the two characteristics being independent there is no tendency *for these averages to move up or down as the* temperature changes If we know the temperature of the week we obviously cannot state the number of deaths in that week with any accuracy We can, however, attempt to do so and we can measure the amount of our error The best estimate of the deaths we can make at any weekly temperature is the average number of deaths taking place in all the weeks put together—for as pointed out we have no reason to suppose that the deaths recorded in a specified week will be more or less numerous than the average, merely because the temperature was high or low Our error in a specified week is, therefore, the difference between the mean number of deaths in all weeks and the number of deaths that actually occurred in that particular week, e g , the mean number of deaths in all the weeks recorded in Fig 8 was 125, in one week with a mean temperature of 36° the number recorded was 50, and our error of estimation for this week is $125-50 = 75$ We can compute this error for each week in turn and find the average size of our error, or, preferably, we can find the average of the squared errors This latter value will, in fact, be the square of the standard deviation of the weekly numbers of deaths (which, as shown previously, is the mean squared deviation of the observations from their average) Our weekly errors between estimation and observation can therefore be measured by σ^2

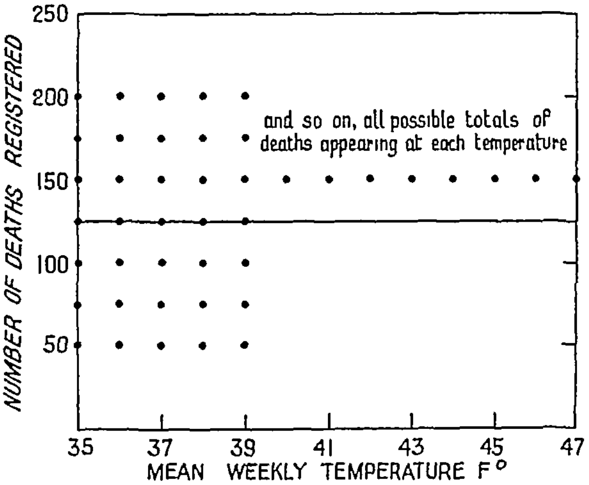

FIG 8 —Number of deaths registered in each week with varying mean temperatures Hypothetical case of complete absence of correlation

(iii) Now let us suppose that neither of the extreme cases is present—i e , neither complete dependence nor complete independence—but that we have something between the two, as in Fig 6, where the deaths certainly decline as the temperature rises but show some variability at each temperature How precisely can we now state the number of deaths when we know the temperature ? Let us draw through the points a line which represents, broadly their trend From that line we can read off the expected number of deaths at each temperature and compare it with the observed number in that week The difference will be the error we make in using this line We can calculate this error for each week and the average of these squared errors we can call S^2

Are we any better off in our estimations of the actual weekly deaths by the use of this line than when we say that in each week we expect to see the average number of deaths that took place in all the weeks ? We can measure our relative success by comparing σ^2 with S^2 *If the two characteristics are entirely independent* of one another (as in Fig 8) the line we draw can have no slope at all and will pass at each temperature through the average number of deaths in all the weeks (there is nothing to make it higher or lower than the average at different temperatures) S^2 and σ^2 will then be the same If the two characteristics are completely *dependent*, as in Fig 7, then there is no scatter round the line at all and S^2 becomes 0 In practice we use as a measure of the degree of association $\sqrt{1-\frac{S^2}{\sigma^2}}$ which is known as r or *the correlation coefficient If no* association at all exists S^3 and σ^2 are, as pointed out, equal and r equals 0 If there is complete dependence S^2 is 0 and r equals 1 For any other degree of association r must lie between 0 and 1, being low as *its value approaches 0 and high as it approaches 1*

The Use and Meaning of the Correlation Coefficient

The actual mode of calculation of the correlation coefficient is fully described in numerous statistical text books, and attention will be confined here to its use and meaning It is calculated in such a way that its value may be either positive or negative, between $+1$ and -1 Either plus or minus 1 *indicates complete dependence of one characteristic* upon the other, the sign showing whether the association is direct or inverse, a positive value shows that the two characteristics rise and fall together—e g , age and height of school children, a negative *value that one falls as the other rises*, as in our example of deaths and temperature In the latter instance the value of the coefficient is, in fact, -0.90 This figure shows that there is in this short series of observations a very high degree of relationship between the temperature and the deaths, but, as it and the graph make obvious, not a complete relationship Other factors are influencing the number of deaths as well as the temperature If we knew the equation to the line we could certainly predict the number of deaths that would take place in a particular week with a given mean temperature with more accuracy than would be possible without that information, *but the diagram shows that in individual weeks we* might still be a long way out in our prediction It is the original variability in the number of deaths at *each* temperature than makes it impossible for the prediction to be accurate for an individual week, though we might be able to predict very closely the *average* number of deaths in a group of weeks of the same temperature The advantage of the coefficient is, as previously pointed out, *that it gives in a single* figure a measure of the amount of relationship For instance, we might calculate two such coefficients between, say, mean weekly temperature and number of deaths from bronchitis and pneumonia *at ages 0–5, and between mean weekly* temperature and number of these deaths at ages 65 and over, and thus determine in which of the two age groups are deaths from these causes more closely associated with temperature level We can also pass beyond the coefficient of correlation and find the equation to the straight line that we have drawn through the points Reading from the diagram the straight line shows that at a weekly temperature of 39 F the estimated number of deaths is about 205 at a weekly temperature of 40° F the deaths become about 185 at a temperature of 41° F they become 165 For each rise of 1° F in the mean weekly temperature the deaths will fall according to this line by some 20 deaths In practice the method of calculating the coefficient of correlation ensures that this line is drawn through the points in such a way as to make the sum of the squares of the differences between the actual observations at given temperatures and the corresponding values predicted from the line for those temperatures have the smallest possible value No other line drawn through the points could make the sum of the squared errors of the estimates have a smaller value so that on this criterion our estimates are the best possible

THE REGRESSION EQUATION

The equation to the line can be found from the following formula :—

$$\text{Deaths}-\text{Mean number of deaths}=\begin{matrix}\text{Correlation}\\ \text{coefficient}\end{matrix}\times\frac{\text{Standard deviation of deaths}}{\text{Standard deviation of temperature}}$$
$$\times\,(\text{Temperature}-\text{Mean of the weekly temperatures})$$

where the two means and standard deviations are those of all the weekly values taken together

Writing in the values we know from the data under study this becomes—

$$\text{Deaths}-167{\cdot}038=-0{\cdot}9022\ \frac{64{\cdot}310}{2{\cdot}867}\ (\text{Temperature}-40{\cdot}908)$$

The fraction on the right hand side of the equation equals 20·24 so that we have—

$$\text{Deaths}=-20{\cdot}24\ (\text{Temperature}-40{\cdot}908)+167{\cdot}038$$

Removing the parentheses and multiplying the terms within by −20·24 this becomes—

$$\text{Deaths}=-20{\cdot}24\ \text{Temperature}+827{\cdot}978+167{\cdot}038$$

or finally

$$\text{Deaths}=-20{\cdot}24\ \text{Temperature}+995{\cdot}02$$

The figure −20·24 shows as we saw previously from the diagram that for each rise of 1 F in the temperature the deaths decline by about 20 (For when the temperature is say 40 F the deaths estimated from the line are 995·02−(20·24) 40 = 185·4 and when the temperature goes up 1 F to 41 F the estimated deaths are 995·02−(20·24) 41 = 165·2)

The figure −20·24 is known as the *regression coefficient* as seen above it shows the change that according to the line takes place in one characteristic for a unit change in the other The equation is known as the *regression equation* As far as we have gone our conclusions from the example taken is that deaths from bronchitis and pneumonia are in a certain area closely associated with the weekly air temperature and that a rise of 1 F in the latter leads on the average to a fall of 20 in the former

Precautions in Use and Interpretation

In using and interpreting the correlation coefficient certain points must be observed.

THE RELATIONSHIP MUST BE REPRESENTABLE BY A STRAIGHT LINE

(1) In calculating this coefficient we are as has been shown presuming that the relationship between the two factors with which we are dealing is one which a straight line adequately describes If that is not approximately true then this measure of association is not an efficient one For instance we may suppose the absence of a vitamin affects some measurable characteristic of the body As administration of the vitamin increases a favourable effect on this body measurement is observed but this favourable effect may continue only up to some optimum point Further administration leads let us suppose to an unfavourable effect We should then have a distinct *curve* of relationship between vitamin administration and the measurable characteristic of the body the latter first rising and then falling The graph of the points would be shaped roughly like an inverted U and no straight line could possibly describe it Efficient methods of measuring that type of relationship have been devised—e g the correlation ratio—and the correlation coefficient should not be used Plotting the observations as in Fig 6 relating to temperature and deaths from bronchitis and pneumonia is a rough but reasonably satisfactory way of determining whether a straight line will adequately describe the observations If the number of observations is large it would be a very heavy test to plot the individual records but one may then plot the *means of columns* in place of the individual observations—e g the mean height of children aged 6–7 years was so many inches of children aged 7–8 years so many inches—and see whether those means lie approximately on a straight line

THE LINE MUST NOT BE UNDULY EXTENDED

(2) If the straight line is drawn and the regression equation found, it is dangerous to extend that line beyond the range of the actual observations upon which it is based. For example in school-children height increases with age in such a way that a straight line describes the relationship reasonably well But to use that line to predict the height of adults would be ridiculous If, for instance at school ages height increases each year by an inch and a half that increase must cease as adult age is reached The regression equation gives a measure of the relationship between certain observations to presume that the same relationship holds beyond the range of those observations would need justification on other grounds

ASSOCIATION IS NOT NECESSARILY CAUSATION

(3) The correlation coefficient is a measure of *association* and in interpreting its meaning one must not confuse association with causation Proof that A and B are associated is not proof that a change in A is directly responsible for a change in B or vice versa There may be some common factor C which is responsible for their associated movements For instance in a series of towns it might be shown that the phthisis death rate and overcrowding were correlated with one another the former being high where the latter was high and vice versa This is not necessarily evidence that phthisis is due to overcrowding Possibly and probably towns with a high degree of overcrowding are also those with a low standard of living and nutrition This third factor may be the one which is responsible for the level of the phthisis rate and overcrowding is only indirectly associated with it It follows that the meaning of correlation coefficients must always be considered with care whether the relationship is a simple direct one or due to the interplay of other common factors In statistics we are invariably trying to disentangle a chain of causation and several factors are likely to be involved Time correlations are particularly difficult to interpret but are particularly frequent in use as evidence of causal relationships—e g the recorded increase in the death rate from cancer is attributed to the increase in the

consumption of tinned foods Clearly such concomitant movement might result from quite unrelated causes and the two characteristics actually have no relationship whatever with one another except in time Merely to presume that the relationship is one of cause and effect is fatally easy, to secure satisfactory proof or disproof, if it be possible at all, is often a task of very great complexity

THE STANDARD ERROR

(4) As with all statistical values the correlation coefficient must be regarded from the point of view of sampling errors In taking a sample of individuals from a universe it was shown that the mean and other statistical characteristics would vary from one sample to another Similarly if we have *two* measures for each individual the correlation between those measures will differ from one sample to another For instance, if the correlation between the age and weight in all school children were 0 85, we should not always observe that value in samples of a few hundred children, the observed values will fluctuate around it We need a measure of that fluctuation, or, in other words, the standard error of the correlation coefficient Similarly if two characteristics are not correlated at all so that the coefficient would, if we could measure all the individuals in the universe, be 0, we shall not necessarily reach a coefficient of exactly 0 in relatively small samples of those individuals The coefficient observed in such a sample may have some positive or negative value In practice we have to answer this question could the value of the coefficient we have reached have arisen quite easily by chance in taking a sample, of the size observed, from a universe in which there is no correlation at all between the two characteristics? For example in a sample of 145 individuals we find the correlation between two characteristics to be +0 32 Is it likely that these two characteristics are not really correlated at all, that if we had taken a very much larger sample of observations the coefficient would be 0 or approximately 0? It can be proved that if the value of the correlation coefficient in the universe is 0, then (*a*) the *mean* value of the coefficients that will be actually observed if we take a series of samples from that universe will be 0, but (*b*) the separate coefficients will be scattered round that mean, with a standard deviation, or standard error, of $1/\sqrt{N-1}$, where N is the number of individuals in each sample In the example above the standard error will, therefore, be $1/\sqrt{144}$ = 0 083 Values which deviate from the expected *mean* value of 0 by more than twice the standard deviation are, we have previously seen, relatively rare Hence if we observe a coefficient that is more than twice its standard error we conclude that it is unlikely that we are sampling a universe in which the two characters are really not correlated at all In the present case the coefficient of 0 32 is nearly four times its standard error, with a sample of 145 individuals we should only very rarely observe a coefficient of this magnitude if the two characters are not correlated at all in the universe We may conclude that there is a "significant" correlation between them—i e, more than is likely to have arisen by chance due to sampling errors If on the other hand the size of the sample had been only 26 the standard error of the coefficient would have been $1/\sqrt{25} = 0\ 2$ As the coefficient is only 1 6 times its standard error we should conclude that a coefficient of this magnitude might have arisen merely by chance in taking a sample of this size and that in fact the two characters may not be correlated at all We should need more evidence before drawing any but very tentative conclusions This test of "significance" should be applied to the correlation coefficient before any attempt is made to interpret it Somewhat more intricate methods are needed to test whether one coefficient differs "significantly" from another—e g, whether deaths from bronchitis and pneumonia are more closely correlated with air temperature at ages 0–5 years than at ages 65 and over (see, for instance, The Methods of Statistics By L H C Tippett London Williams and Norgate Ltd 1931 15s)

Summary

The correlation coefficient is a useful measure of the degree of association between two characteristics but only when their relationship is adequately described by a straight line The equation to this line, the regression equation, allows the value of one characteristic to be estimated when the value of the other characteristic is known The error of this estimation may be very large even when the correlation is very high Evidence of association is not necessarily evidence of causation, and the possible influence of other common factors must be remembered in interpreting correlation coefficients It is possible to bring a series of characteristics into the equation, so that, for instance, we may estimate the weight of a child from a knowledge of his age, height, and chest measurement, but the methods are beyond the limited scope of these articles

A B H

CORRIGENDA —In last week s article the formula in line 17 of the second column of p 527 should read $n=(c-1)(r-1)$ and the numerator of the fourfold table on p 528 should read $(ad-bc)^2\ (a+b+c+d)$

KING'S COLLEGE HOSPITAL NEW WING —On Feb 23rd Viscount Wakefield, vice president of the hospital, opened a wing for private patients which has been presented to the hospital by the Stock Exchange Dramatic and Operatic Society and by other friends on the Stock Exchange The building is 266 feet long and 80 feet wide and runs parallel with the main corridors of the hospital The offices are on the side nearest to the hospital so that accommodation for the patients is separated from sounds connected with its work, but there is direct access to the X ray and other special departments in the main building Above the entrance rises a tower 70 feet high in which are situated the suite of rooms for the resident medical officer and a muniment room for the safe custody of records, it is a memorial to the flight of Mr Giles Guthrie from England to Johannesburg erected by his father, Sir Connop Guthrie On the first floor there are eighteen single rooms for which the charge will be 8 guineas a week. The patient makes his own arrangement for the payment of fees for professional attendance, including the services of the pathologist and radiologist In close proximity to the floor is an operating theatre specially provided for visiting surgeons On the floor above is a complete maternity unit where accommodation is provided at varying charges ranging from 7 to 10 guineas in rooms with one, two, and four beds The services of the resident medical officer will be available for antenatal attention as well as for the confinement, and a comprehensive fee can be arranged to cover both On the floor above is a maternity isolation unit In order to provide the additional staff for the new wing it has been necessary to extend the accommodation for resident medical officers, nurses and maids On these extensions there is a debt outstanding of £15,000 The sum of £8000 would enable the ground floor to be fitted up as a dental department readily accessible from the out patient department, which would release the general ward of the hospital where it is at present housed for occupation by ordinary patients

SPECIAL ARTICLES

HUNTER THE GREAT RESEARCHER *

By Lord Horder M.D K.C V O

On Monday in last week Lord Horder delivered the Hunterian Oration before the Hunterian Society It will appear in full in the *Transactions* of the Society and was a *masterly little disquisition* on the ideals and performances of the great researcher The orator came straight to his subject in the following way :—

Hunter was not *only* a surgeon—it might sound *invidious if I said not a mere surgeon* —he was a physician also and a better physician in many respects than some of his contemporaries who practised in that branch of medicine But more than either of these two things he was first and foremost, a pathologist *in the best and in the only true sense of that* word—a man who sought out the causes and the nature of diseases He was also as we know a great anatomist and physiologist, and he made these two fields of research so wide that they embraced the whole *animal kingdom Hunter's anatomy* and physiology were as we term it comparative as well as human I suppose no man ever spread his net wider than he did in his effort to read a little in Nature s infinite book of secrecy What he was after however and the little (as he would have thought it) that he did was bound up with pathology a branch—shall I not say the root ?—of surgery which, before him, scarcely existed. Even the physician s branch of medicine had precious little real science to support it so that the whole of medicine gained greatly through Hunter's work

TECHNICIAN AND PHILOSOPHER

"Sir D Arcy Power in his Hunterian Oration before the Royal College of Surgeons of England used the phrase the Hunterian tradition by which to express a dual legacy left by Hunter to our profession—namely his technical and pathological trend which he gave to the study of surgery and it was the latter part of his dual legacy with which I will deal disclaiming any intention of estimating Hunter's technical ability as surgeon I am convinced that whatever the degree of his technical skill this was of far less moment as a gift to humanity than the opening up of that vast field of observation and investigation in pathology which laid the foundation for the surgery of the future. It does not appear that he himself introduced much by way of new operations nor laid down new principles by way of surgical technique The one great exception to this statement is his method of curing aneurysm of the popliteal artery This was a much more common disease in his day than it is in ours and before Hunter the current surgical treatment was to tie the dilated vessel above and below the sac and so obliterate it Hunter relying upon the adequacy of the collateral circulation in the leg below the knee introduced the method of tying a single ligature round the artery in the thigh and allowing the aneurysm to shrink This operation said to have saved thousands of limbs and lives spread Hunter's fame more than anything else that he did for it quickly superseded the old operation all over Europe Its introduction was the direct result of work in many fields; in it he united a whole multitude of facts from anatomy physiology clinical experience post mortem examinations and experiments on animals Surgery before Hunter—what was it ? The same old system that the Egyptians knew—making holes to let the evil spirits out Phlebotomy was no more purges and clysters—called by another name to day—have carried on the same notion but for evil spirits read auto intoxication

Lord Horder then pointed out that after Hunter a great change took place in the studies of surgeons who following him in the pursuit of science became the chief anatomists equal as physiologists and pathologists with the physicians who had previously held the scientific field Undue stress he thought seems to have been laid upon whether Hunter proceeded in his researches mainly by deduction or by induction while the conflict of philosophical methods led to confusion of thought and obscurity of language. The known tendency of the Scotch thinker is he said to proceed deductively and of the English thinker to proceed inductively and it seems to have been assumed that the Scotsman working in London would find his native mental equipment embarrassed Experience of which there is quite a considerable amount does not support this view

It is idle to speculate what would have happened if Hunter had gone to a Scotch University and had been educated One possibility is that medicine would have lost John Hunter and been so much the poorer He was of course chiefly inductive in his methods The orator pointed out that Plato Aristotle Hippocrates Galen and Celsus in sequence had followed the deductive method constructing dogmas and theories from the most meagre facts and he suggested that the systematic reform of medical philosophy dated from Bacon as an intelligent attempt to place the investigation of nature on a solid foundation Hunter's excursions into deduction he said, led to no scientific advance

But in induction he did much better He anticipated the recapitulation theory of Haeckel by pointing out that the embryo in each successive stage of its existence resembles the completed form of some lower order than itself He concluded from a large number of studies that abnormalities are an expression of *arrested development* He seemed also to anticipate Darwin in his teaching that structure is the ultimate expression of function and not vice versa. He was fond of teaching that the blood is alive and though here again he seems to be flirting with an old *a priori* vitalistic speculation he seems nearly to have stumbled upon a very modern conception And he got as near to Pasteur and Lister from sheer experimental evidence as to say that air of itself has no power to excite inflammation But though these examples show that Hunter was capable of taking the results of his inquiries into general conclusions he was chary of doing so As for abstractions which *sought to take the place of* demonstrable facts his well known advice to his pupil Jenner sufficiently repeats his own favourite method. Don t think—try; be patient be accurate

JENNER AND HUNTER

Lord Horder gave an interesting account of the close association between Jenner and Hunter based on the long correspondence which took place between them which he said epitomised the spirit the tenacity and industry of Hunter In these letters Jenner was thanked for his experiments with a hedgehog but urged not to ask questions but to try experiments, the problems put before him being so varied as the natural history of a cuckoo, the breeding of toads, the nesting of birds, the temperature of vegetables—"Have you large trees of different kinds that you can make free with? If you have, I will put you upon a set of experiments with regard to the heat of vegetables"—again "Have you any eaves where bats can go at night? If you have, I will put you upon a set of experiments concerning the heat of them at different seasons." "Have you got the bones of a large porpoise? Is ever the salmon spawn seen after she has parted with it?"

---

* Abstract of the Hunterian Oration delivered before the Hunterian Society on Feb 22nd

In the course of this correspondence with Jenner it became known to Hunter that Jenner had in some way lost the affections of the "woman of fortune" on whom he had set his hopes. Hunter's condolence, and also his effort at consolation, are both characteristic. . . . "I own I was at a loss," he writes, "to account for your silence, and I was sorry for the cause. I can easily conceive how you must feel, for you have two passions to cope with, that of being disappointed in love, and that of being defeated; but both will wear out, perhaps the first soonest. . . . but 'let her go, never mind her.' I shall employ you with hedgehogs. . . . get a hedgehog in the beginning of winter, and weigh him; put him in your garden . . . then weigh him in the spring and see what he has lost."

THE HUNTERIAN "TRADITION"

Lord Horder continued: "And so, after just 200 years, the tradition comes down to *us*. What are we doing with it? Are we carrying it on? *Can* we carry it on? For that is what matters. Institutions are doing their utmost to carry it on. This Society, as I have remarked; the College of Surgeons, with its great museum—'Hunter's monument,' as the president called it last week—where Wren's telling epitaph would be singularly apt—the enlarged laboratories, the Buckston Browne experimental farm, with its increased equipment, and capable of almost indefinite extension. . . . But what of *us*, the individuals: how is it with *us*? (1) Have we Hunter's power of concentrated industry? Someone has said that genius is as much a matter of perspiration as inspiration, and he must surely believe that if genius is not an infinite capacity for taking pains, at least it takes a genius to exercise this rare quality. I think some of us do possess this power of dogged, persistent effort. When I watch some of my colleagues who are in the van of research at their work I feel ashamed of the laziness of my own mind, the readiness with which it lets go its task, and the ease with which it yields to discursiveness. (2) Have we Hunter's inquiring mind, his lust to know, for the sake of knowing? (3) Have we his intellectual courage? Or do our minds run away when the struggle goes against us? (4) Have we Hunter's spirit of accuracy? Are we, as he was, filled with a divine discontent with any proof except that which carries an inescapable conviction? Remember those cuckoos' stomachs, those hedgehogs—more and more must be examined until the fact we are seeking cannot be avoided. (5) Are we, perchance, saying there is so little left to find out? We know all about hedgehogs—*or do we*?

"We are in a different part of the field, of course, for the pioneers have made a tremendous clearance. But there is probably still as much to be done as ever, though of a different kind. Or do we think that because we are so specialised in our several spheres, and research is therefore much more intensive, our problems are less surmountable than those which Hunter set himself? Tracking down 'elementary bodies' would seem, on the face of it, to be a more stubborn task than discovering the lymphatic system. Heading off a pandemic of influenza, with its almost elemental ravages, and getting its precursors and its 'trailers' and 'settings' accurately taped, seems work for gods rather than mere men. So much easier still to talk about 'epidemic constitutions' and leave it at that. Recognising clearly the factors which go to make a balance, or an 'imbalance,' in a man's hormones, and getting control over this delicate adjustment—surely Hunter never had a task which was the like of this? Solving the riddle of the endocardial infection. Understanding the mechanism of high and of low arterial pressures. Diagnosing cancer before as yet it yields what we call 'physical signs' or suggests its presence by recognisable deviations from the average in the radiologist's shadow pictures. Determining sex. Preventing a whole heap of diseases which, once established, we cannot cure."

THE STRESS OF TO-DAY

The orator concluded by pointing out that these problems were for us to-day. "We have a corpus of knowledge to draw upon, completely hidden from Hunter, but are deflected by the domination of the age. Life has us by the throat. We are caught between instinct and reason; we have let go the former but we have not yet got a sure hold upon the latter; we are no longer savage nor are we yet sapient. To 'the intruding rabble of men, and books, and institutions' that broke in upon Emerson's peace we now add a host of new distractions and disturbances. What are we going to do about it? Are we also going to become a mob or are we going to maintain our intellectual freedom? To carry on the Hunterian tradition we must take to heart the Sage of Concord's warning: 'Let us not rove, let us sit at home with the cause. . . . at times the whole world seems to be in a conspiracy to importune you with emphatic trifles. Friend, client, child, sickness, fear, want, charity, all knock at once at thy closet door, and say—"come out unto us." But keep thy state; come not into their confusion.' A few men and women are, I think, bent upon doing so. Unlike 'those who went upon the Holy Quest' they are not 'lost in the quagmire' nor do they follow 'wandering fires.' If only the politicians can keep the ring for them. God help them to do so! I suppose politicians do *know* how important these things are, how vital to all of us and to the future? When Pitt was approached with the object of getting the government of his day to purchase Hunter's unique collection of specimens he is reported to have said: 'What! Buy preparations? Why I have not money enough to purchase gunpowder!' History repeats itself. At first thought it would seem foolish to grudge the exchange of scientific inquiry for bombing planes, seeing that others have decided that if it is to be guns or butter then it is to be guns. But at second thought comes wisdom, and we remember that even dictators are transient, if not trivial, whereas these other things are eternal. Surely it is better to know the behaviour of a cuckoo's stomach than to organise a nation for war? Dr. Johnson once said that 'the man who is growing great and happy by electrifying a bottle wonders to see the world engaged in the prattle about peace and war.' The thought is the same (and I have the satisfaction of knowing that on this occasion I had expressed mine before I came across Dr. Johnson's). I feel quite sure that if John

Hunter were amongst us to-day he would risk the same charge of simplicity or of impertinence as did Johnson's physicist. Nor would he be ashamed if the gas-bomb found him so occupied.

Cannot you *see* this little man (Hunter stood 5 ft 5 in. in his boots) with his shock of red hair, his exuberant vitality, his restless curiosity, making his attack upon the new world of facts, probing, measuring, comparing, his tools so rudimentary, his methods all his own, grappling Nature, laying her under tribute, wrestling with her like Jacob with the angel, and saying, as Jacob said, "I will *not* let thee go except thou bless me."

"Let us imagine he *is* here, as indeed he is, living on amongst us in the tradition that he left behind him. Let us be worthy of him and of it.

MEDICINE AND THE LAW

The Counting of Swabs

AN inquest at St Albans last month raised two points of some importance. A married woman had entered the Hill End Hospital as a patient in 1922. Her husband, who had not seen her for ten years, told the coroner that he consented to a surgical operation being performed upon her about 14 months ago; he was afterwards informed that the operation had been successful. On Feb. 2nd, 1937, the patient died. Post-mortem examination showed that death was primarily due to myocardial degeneration; there was also localised peritonitis, probably set up by the presence of a small gauze swab lightly attached to the intestines and accompanied by a small pocket of pus. So far as was known the deceased had undergone only one operation. The surgeon who, under arrangement with the Herts County Council, had operated on the patient described the routine work of using and checking swabs; it was, he said, the duty of the nursing staff to check them and the operating surgeon was obliged to rely on the nurses in this respect. The assistant matron of the hospital, in charge of the operating theatre on the occasion concerned, explained how she had checked the swabs in bundles of ten, handed clean ones as required and counted the dirty swabs thrown away into a bucket. She could not now say how many were then used. She was satisfied that every swab used at the operation had been accounted for. A hospital sister who assisted the previous witness confirmed the checking and counting: her evidence indicated that, if any mistake had occurred, both she herself and the assistant matron must have made the same mistake.

The first point of medico-legal interest, therefore, was the fact that the inquest provided one more occasion for speculation whether the responsibility for checking the swabs lies with the nursing staff or whether the surgeon, who puts them in, has a legal duty to see that they are all taken out. In other words, do the surgeon and nurses act as a team or does the surgeon remain solely liable? A swab inadvertently left in the patient's body is a potential danger. Is the mere fact of its presence in the body conclusive evidence of negligence, or is it merely prima facie evidence? In Crotch *v.* Miles (*Lancet* 1930, i, 717) Lord Hewart told the jury that it might well be that, in the actual course of the operation, while the surgeon was cutting and opening and attending to his surgical task, it was neither to be expected nor desired that he should be busying his mind with the counting of every swab and forceps or with the question whether one was missing. Lord Hewart however offered the jury the suggestion that they might possibly think it part of the surgeon's duty to concern himself with that inquiry at the close of the operation. "It may well be that any delay would be prejudicial if it occurred before the body of the patient was stitched up, but you may think that afterwards, before the surgeon departs, it is reasonable that he should personally satisfy himself that the number is correct and that there is nothing missing." The jury, therefore, in Lord Hewart's view, had to decide upon the particular facts of the case whether there had been negligence on the part of the surgeon or not. The legal position still awaits amplification.

The second point in the St Albans case arose out of the statutory duty to report the cause of death. Every death in a lunacy institution within his jurisdiction, said the coroner, had to be notified to him within the prescribed time, so that he might consider whether the facts required inquiry. No mention was made in the report from the hospital to the coroner of the discovery of the swab. The pathologist who made the post-mortem examination had been in doubt whether the prescribed form of report contained any particular place where the information could have been appropriately entered. The details entered on the form were settled in discussion between the pathologist and the medical superintendent. There was clearly no intention to conceal facts from the coroner, since the medical superintendent personally reported the full circumstances to him; the pathologist, when filling in the form, was aware that this oral report was being made. Had it been desired to keep the facts from the coroner the coroner would be unaware of them to-day. The coroner explained to the jury the necessity of complete information being given to him. He probably had in mind that Form 33 appended to the Mental Treatment Rules asks for the immediate cause of death, the morbid conditions (if any) giving rise to the immediate cause and the other morbid conditions (if important) contributing to death but not related to the immediate cause. Form 10 also, the post-mortem record, provides a space for "any special notes." The jury returned a verdict of "death by misadventure"; nothing was said of any negligence on the part of the surgeon. The coroner indeed had gone so far as to say that an operating surgeon could hardly be asked to count and check swabs but should be allowed to leave these details to the persons specially trained and trusted for this purpose.

Allegation of Negligence Withdrawn

An allegation of professional negligence was handsomely abandoned by plaintiff's counsel on Feb. 22nd before Mr Justice Lawrence, although, as this step was not taken till the case was called on for trial, the defendants must first have been put to considerable trouble and expense in preparing their defence. The action was brought against the Governors of the Royal Masonic Hospital at Ravenscourt Park and also against the house-surgeon, in spite of the fact that he had neither advised nor performed the operation which gave rise to the case. The plaintiff (on behalf of herself and her infant son) claimed damages in respect of the death of her husband. When the patient was admitted to hospital it was considered that the only chance of saving his life lay in an immediate operation. A specialist performed it, but the patient's condition was such that he died two days later. The plaintiff complained that the operation had been negligently performed and that since the patient had not consented to it, there had been an actionable assault Plaintiff's counsel frankly admitted that the claim would, at the best, have been a difficult one but, by the time the hospital's records and documents had been examined, "it became apparent that not only was there no hope of succeeding but no ground whatever for proceeding with the claim" All allegations were withdrawn, the hospital took judgment with costs but does not propose to enforce them against the widow Every successful resistance to claims based on suggestions of professional negligence does service to the profession as a whole

Mushroom Poisoning

Not long ago a plaintiff succeeded in obtaining damages for food poisoning in a case where the connexion between the menu and the illness was not conspicuously clear In Harris *v* J Lyons and Co, decided last week, the plaintiff had eaten a meal including mushrooms one evening at one of the defendant company's restaurants He felt very ill in the middle of the night, he suffered from a painful affection of the skin, and his medical attendant, having heard what the patient had eaten, diagnosed mushroom poisoning He formed that opinion, in the words of Mr Justice Swift, with perfect honesty and professional propriety Two doctors called for the defence, however, disagreed with this diagnosis Both were experienced in mushroom poisoning and its effect on the skin, in their view Mr Harris was suffering from erythema *multiforme* With this conflict of evidence, said the judge, it was impossible for the court to hold that without any doubt Mr Harris was suffering from mushroom poisoning There was a doubt, and Mr Harris, not having discharged the onus of removing the doubt, could not succeed The defendants, not content with relying upon the failure of the plaintiff's case, offered a mass of evidence to rebut the suggestion of negligence They could not allow a customer to say that a dinner in one of their restaurants meant an illness They gave the life-history of their mushrooms from the first chapter of the sterilised spawn in carefully superintended beds at Worthing to the last chapter when the chef at Olympia prepared the dish for table The judge announced that no negligence could be attributed to the defendants They had been most careful. He was sorry for the pain Mr Harris had suffered, but the court could not dip its hand into the company's pocket to award compensation to Mr Harris unless satisfied that the company was responsible for Mr Harris's condition Mr Harris had failed to prove that post hoc was also propter hoc

---

PARIS

(FROM OUR OWN CORRESPONDENT)

EARLY DIAGNOSIS OF UNDULANT FEVER

THE undulant fever research centre at Montpellier has issued a report by R M Taylor, M Lisbonne, and L-F Vidal on the symptomatology of the disease as shown in 333 cases in which the diagnosis was confirmed by serological tests or blood culture In 135 cases *Brucella melitensis* was grown from the blood, and in 8 cases *Br abortus bovis* The nine most prominent clinical manifestations were asthenia, fever, excessive perspiration, attacks of shivering, anorexia, constipation, insomnia, pain in the joints and muscles, and irritability Asthenia was noted in every case, fever in 99 per cent, and irritability in 41 per cent When these nine manifestations were classified according to the stage of the disease at which they first appeared, asthenia was found to be the earliest and irritability the latest A classification of 322 cases according to the diagnoses first made demonstrated a high proportion of mistakes In 90 cases the doctors first consulted had been prudent enough to leave the diagnosis open. In the remaining 232 cases the diagnosis was usually made with more promptness than accuracy, for among the early diagnoses only 89 correctly attributed the illness to undulant fever In as many as 71 cases (31 per cent) the initial diagnosis was influenza, next came infection of the respiratory tract (19 cases), and typhoid or paratyphoid fever (16) Other mistaken diagnoses included articular rheumatism, sciatica, meningitis, orchitis, and neurasthenia—which illustrated the polymorphism of the disease, not to mention the diagnostic versatility of the practitioners concerned There were only four cases in which malaria had been incorrectly diagnosed, but as Dr Taylor and his colleagues point out, this figure would assuredly have been much higher had malaria been endemic in the neighbourhood

LICENSED PROSTITUTION

M Henri Sellier, Minister of Public Health, is already encountering opposition to his proposal to add France to the abolitionist countries A speech recently delivered at Lyons by Dr C Fouqué was a glowing, almost apostolic, defence of the licensed brothel and of its occupants Lyons, by the way, has an interesting system of medical supervision of prostitution devised and practised by two doctors in this town, and the alleged efficacy of this system was one of the arguments advanced by Dr Fouqué in support of the old order of things A perusal of his speech, reported at considerable length in the *Siècle Médical* for Feb 15th, must induce many a reader to marvel. It appears that Dr Fouqué is a convinced believer in Lombroso's conception of certain women fated from birth to become prostitutes While all men are supposed to be polygamous by instinct if not in act, and most women are supposed to be monogamous by circumstance if not by instinct, there is this Lombroso discovered type whose functions are apparently as valuable as they are innate Dr Fouqué spoke of this born prostitute as of one who must always be treated with kindness and solicitude, "almost with respect, for she accomplishes, unconsciously perhaps, a social role of the greatest utility" If M Sellier's opponents are to take their cue from such a speech as this, with its emotional bias and its avoidance of such disagreeable facts as are to be gleaned from the abolitionist countries, he may count himself happy, for the French are essentially logical.

CHLORINATION OF THE DRINKING WATER

The vital statistics of Lyons make instructive reading in view of the verdunisation of the city's drinking water The general mortality in 1936 was 10 35 per 1000 inhabitants, whereas the average for the five years preceding the introduction of chlorination was 13 Between the ages of 0 and 20 there has been a decline in the general death rate by 47 per cent within the same two periods As for the typhoid mortality, it has been reduced from 3 to 1 per 100,000 inhabitants The behaviour of the death rates in Paris before and after the introduction of chlorination is remarkably similar to that of Lyons, and a campaign is now afoot in favour of compulsory chlorination of the main supplies of drinking water throughout the country

MEDICINE STAMP DUTIES

REPORT OF SELECT COMMITTEE

LAST November fifteen members of the House of Commons were appointed to consider the duties of excise chargeable under the Medicines Stamp Act, 1802 the Stamp Act, 1804 and the Medicines Stamp Act, 1812 and any enactment amending those Acts and to report thereon and make such recommendations for the alteration of those duties or otherwise as they thought fit with a view to re forming the law relating thereto This select committee freely used its powers to send for persons papers, and records, and its report was issued last week (H.M. Stationery Office. 3d)

CONCLUSIONS

The committee came unanimously to the following conclusions —

(1) That the existing Stamp Acts, passed over 100 years ago are out of date largely obsolete and quite inappropriate to modern requirements.

(2) That owing to out-of-date exemptions and to a number of judgments in the courts, wholesale avoidance of duty has been practised which has led during the last nine years, to a remarkable decrease in the yield of the duty (nearly 50 per cent)

(3) That the law should be simplified thus removing those obscurities which at present give rise to numerous anomalies and add greatly to the difficulties of administration.

(4) That in spite of some evidence to the contrary the trade in medicinal articles is in their opinion one which is suitable for taxation

(5) That the rate of duty should be lowered particularly in the lower ranges, and more evenly graduated

(6) That it is undesirable that the same product should be sold by different vendors stamped and unstamped

(7) That a far larger range of preparations should be made liable to duty

RECOMMENDATIONS

Arising out of these conclusions the committee recommends :—

(1) *Repeal* —That the Acts of 1802 1804 1812 Section 2 of the Finance Act 1927 and all other existing legislation on the subject of Medicine Stamp Duties be repealed

(2) *Dutiable articles* —That, subject to the *exemptions* mentioned below the articles in the following list should be liable to a duty based on the retail selling price :—

Preparations or substances of any sort, including medicines, medicaments medicated articles drugs herbs fumigants inhalants disinfectants antiseptics soaps, tooth pastes tooth powders mouth washes medicated wines natural or artificial mineral waters or compositions for making such waters confectionery toilet preparations and cosmetics to be used or applied externally internally or otherwise as medicines or medicaments which are recommended held out or advertised in any way whatsoever either directly or indirectly (whether by public display wireless telephony or other mechanical reproduction of the human voice or by label notice circular or other written recommendation or otherwise) for the prevention cure or relief of any human ailment defect disorder condition or habit or for the treatment of any part of the human body or for the protection or maintenance of bodily health.

(3) *Duty scale* —That the present scale of duties should be revised as follows —

Retail price excluding duty		Rate of duty
Exceeding	Not exceeding	
—	¾d	⅛d
¾d	1½d	¼d
1½d	3d.	½d.
3d	6d.	1d.
6d		*1d for the first 6d and 1d for every 6d or part of 6d over 6d

The committee was much inclined to recommend a direct ad valorem sales tax of 16⅔ per cent —i e 2d in the 1s —but was persuaded that this would be more difficult to administer and would cause more disturbance to existing prices and other arrangements of manufacturers.

(4) *Excise licence.*—That the licence of 5s per annum be continued as heretofore

(5) *Exemptions* —That exemptions be granted to—

(*a*) all medicines &c. (as set out above) recommended and sold solely and exclusively to registered members of the medical or dental professions;

(*b*) all preparations, &c supplied to registered medical or dental practitioners for use in the discharge of their professional duties also all preparations, &c supplied to registered pharmacists or registered medical or dental practitioners for use in dispensing as a component part of medicines prescribed by such practitioners

(*c*) all medicines, &c exported for use or consumption abroad and

(*d*) all British spa waters consumed only at the place of origin.

FURTHER SUGGESTIONS

The committee went on to urge consideration of the propriety of taxing foods and certain appliances (such as deaf aids) beverages (alcoholic and otherwise) and other preparations widely advertised as possessing properties beneficial for health If it is found difficult to distinguish between cosmetics which claim to be remedial and those which do not the best course might be to tax all cosmetics

Should control of the trade in medicines and appliances be deemed desirable for the protection of the public the committee believes that the best method of achieving this would be a system of examination and registration of all advertised medicines and appliances

CONTROL

The committee endeavoured to limit its inquiry as far as possible to the fiscal aspect of the question Strong opinions were, however expressed by certain witnesses in the course of the inquiry that some form of control of the medicine trade was desirable to safeguard the public from fraudulent exploitation Authoritative statements were made to the effect that people (largely the poorer and less well-educated) spend more money than they can afford on remedies of little or no efficacy with an accompanying indirect danger to health as a result of their not seeking medical or surgical treatment in time "Though we have reason to believe the report runs that matters are not as bad as they were we are strongly of opinion that the appeal to fear which is the underlying motive of large numbers of advertisements not only of medicines in the strict sense but of such articles as those referred to at the beginning of paragraph 6 is psychologically harmful. The reference here is to products such as tonic foods beverages appliances, meat extracts cereals bread and even mustard which though not strictly medicines are widely advertised in effect for the relief cure or prevention of some human ailment.

PARLIAMENTARY ELECTION FOR THE COMBINED ENGLISH UNIVERSITIES

THERE will shortly be an election for the representation in Parliament for the Universities of Durham, Manchester, Liverpool, Leeds, Sheffield, Birmingham, Bristol, and Reading Nomination day is to day, March 5th, and polling will commence on Monday, March 15th. Sir Henry Brackenbury, a vice president of the British Medical Association and of the Association of Education Committees, is standing as an independent, Sir Francis Lindley, recently ambassador extraordinary to Japan, as the national conservative and constitutional candidate, Mr T E Harvey, formerly M.P for West Leeds, as an independent progressive, and Mr F O Darvall, director of research and discussion for the English Speaking Union, as an independent candidate to the extent that he will not accept any party whip but at the same time will give general support to the National Government In his election address, Sir Henry Brackenbury, the only medical candidate, says —

"The main hope for the future of this country is the cultivation of childhood and the full development of all its immense potentialities The chief care of the nation should be to help and encourage motherhood and to make it as safe as possible, and to secure for children, even from the prenatal stage up to full adolescence, such a physical and mental environment as will permit of the development of a complete and many sided personality I appreciate the efforts which the present Government have made and are still making to these ends, but bolder, more continuous, and more coördinated efforts are required A fuller and integrated scheme for a national maternity service is immediately necessary Nursery and open-air schools should be further encouraged, and many of the older school buildings should be radically altered or replaced The provision of playing fields, gymnasia, and swimming baths should be facilitated Restrictive regulations on secondary school buildings, made when economy was urgently required, should be rescinded, in the planning of new schools, both elementary and secondary, due regard should be paid to the provision of suitable and sufficient dining hall and kitchen accommodation A larger proportion of specially qualified, trained, skilled teachers is required in most schools, not least in those for infants and junior scholars and for retarded children The coming considerable fall in the number of children of school age should not be used for an immediate reduction in teaching staffs, but rather as an opportunity for securing smaller classes and a higher proportion of teachers to children It should be made possible for teachers to take their due share in public life"

On the urgent question of nutrition, while pointing out that there are no exact criteria by which degrees of nutrition can be measured, Sir Henry points out that recent statistics show that in the elementary schools there are definite proofs of under nourishment, while the inter relationship between physical training and nutrition and mental training is so close that they cannot properly be separated He says

"I am in full sympathy with the proposals of the present Government in this regard I was a member of the Executive Committee of the Central Council of Recreative Physical Training and of the Special Committees of the British Medical Association on Nutrition and on Physical Education which have had so profound an effect in guiding public opinion and formulating policy on these questions I hope that experience gained in these investigations and surveys might prove useful in the designing of practical measures for development The gaps still remaining in the continuity of care for children and young persons should be filled and the permitted hours of labour of those who have entered industry shortened The dependants of persons insured under the National Health Insurance Acts should be included in that health system, and some needed extensions and improvements of that service should be effected Indeed, the time is ripe for the initiation of a comprehensive general medical service for the nation based upon the prevention of disease, the promotion of positive health, and the provision of skilled medical care and attention, both general and specialist, for those who are ill Such a scheme should be established after full consultation with the medical profession The need for the care of mental health, especially for those distressing conditions of fear, anxiety, obsession, and the like, both in children and adults, which cause about one third of the incapacitating illness of the country, is quite as great as that for attention to physique and to bodily ills

"Biological, psychological, and medical research into many aspects of maternity, mentality, and educational methods as well as research into various branches of technology and agriculture, should be more fully aided by the State, preferably under the auspices of the universities of the country"

Pointing out that a well educated and properly used medical profession is the best safeguard to the public health, Sir Henry stresses the great importance to the public of medical education, a subject with which he has been prominently concerned in many recent inquiries "I am convinced," he says, "that most of the changes in the newly prescribed curriculum will tend to the improvement of what was already good, changes in medical science, social needs, and pedagogic methods are so rapid and significant that continued efforts are required to keep medical education fully adapted to the needs of the community"

Sir Henry concludes his address by affirming his reliance on the League of Nations, whose success in many spheres, he points out, has been far greater than is commonly supposed, certain major failures he holds to point to the greater effectiveness which might be arrived at by a modification of methods

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED FEB 20TH, 1937

Notifications —The following cases of infectious disease were notified during the week Small pox, 0, scarlet fever, 1587, diphtheria, 1156, enteric fever, 30, pneumonia (primary or influenzal), 1881, puerperal fever, 46, puerperal pyrexia, 136, cerebro spinal fever, 45, acute poliomyelitis, 5, encephalitis lethargica, 10, continued fever, 1 (Leatherhead), dysentery, 59, ophthalmia neonatorum, 93 No case of cholera, plague, or typhus fever was notified during the week.

Notifications of acute pneumonia in England and Wales were only 7 per cent above expectation In London itself there were 55 per cent below

The number of cases in the Infectious Hospitals of the London County Council on Feb 26th was 3301 which included Scarlet fever 841 diphtheria 1002, measles 30 whooping cough 571 puerperal fever 18 mothers (plus 10 babies), encephalitis lethargica 283 poliomyelitis 3 At St Margaret s Hospital there were 19 babies (plus 9 mothers) with ophthalmia neonatorum

Deaths —In 122 great towns, including London, there was no death from small pox or enteric fever, 9 (0) from measles, 4 (1) from scarlet fever, 43 (9) from whooping cough, 35 (2) from diphtheria, 39 (12) from diarrhœa and enteritis under two years, and 423 (33) from influenza The figures in parentheses are those for London itself

Of the 339 deaths from influenza in the great towns of England and Wales outside Greater London the largest totals were reported from Liverpool 29 Manchester 25 Birmingham 23 Stoke-on Trent 19 Hull 13 Newcastle upon Tyne and Walsall each 11 Leeds and Middlesbrough each 10 With the sole exception of Leeds all these figures are lower than in the previous week. Corresponding figures for Scottish and Irish towns were Edinburgh 14 Glasgow 12 Dublin 20 Belfast 6—In each case except Belfast a drop on the previous week

Birmingham reported 2 deaths from measles Fatal cases of whooping-cough were scattered over 20 great towns Liverpool reported 7 Manchester 4 Fatal diphtheria was reported from 27 towns 3 from Wolverhampton not more than 2 from any other

The number of stillbirths notified during the week was 268 (corresponding to a rate of 40 per 1000 total births), including 41 in London.

GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations Each contributor is responsible for the section for a month his name can be seen later in the half yearly index

FROM A RUSTICATING PATHOLOGIST

II

WHY do we not save domestic trouble by having meat at one meal and pudding at another or meat on Mondays, Wednesdays, and Fridays pudding on Tuesdays Thursdays and Saturdays, and both on Sundays? Why do we have both approximately twice a day? Women talk a good deal about labour saving in the home though they do not really seem to do much about it. I suspect indeed that what they really want is to get rid of one piece of labour so that they can add or substitute another; electrical carpet-sweepers for example do not actually diminish the amount of work put into cleaning they enable more to be done with the same amount of work and the standard of cleanliness to be raised moreover they have the fascination of a gadget. Anyway any suggestions made by men (who naturally incline towards bestial habits of life) in the way of simplifying the feeding business do not seem to be very welcome Why not use the same plate for successive courses, wiping it up if you like in between with a piece of bread? Well it just isn t done what may be mixed with advantage in vivo would upset the constitution if mixed in vitro though why bacon and marmalade should be more revolutionary than mutton and red currant jelly is hard to see and I did once see a hurried gentleman in an American hotel who had fried eggs waffle cakes and maple syrup for his breakfast and mixed them all up together on one plate, and got outside them in about a minute And when seeing that our Ruby was out and that washing up would presently ensue I proposed that we should clean up our plates a bit and then use the backs I soon felt that the mills of God were grinding very thoroughly This washing too is not what it was for that eminently practical and labour saving device the plate rack is no longer comme il faut each plate has to be wiped dry and polished which bacteriologically is a dirty thing to do compared with putting them up on edge to dry themselves Small wonder that some people take to newspapers

* * *

Now I have the highest respect for the essential soundness of the domestic habits and customs which are imposed on us by our women out of their instinct and accumulated unconscious experience I do not suppose that anyone could prescribe a more perfect diet than what is supplied for her family by a sensible woman who is not restricted by money The tale of modern dietetics is as good a yarn as anyone has ever had to tell and one of its most interesting features is not that it has told us what to eat but that it has explained why we eat what we do To work out such an empirical scheme is a wonderful testimony to woman s capacity to see the connexion between long distance causes and effects which is evidently from the history of the progress of human intelligence not at all an easy thing to do Remembering too what a plight we should have been in if we had all been compulsorily fed by the physiologists say about 1910 I should be very chary about challenging any of our accepted dietetic habits—accepted that is by ordinary people who have enough money not by freaks and reformers In some instances accepted practice seems to be certainly wrong in its development—e g in the idea that what is known as offal to the butchers is no longer genteel whereas we have every reason to suppose that a moderate supply of livers kidneys hearts and with more hesitation haggis is very good for us as a great placard in Manchester used to say The King eats tripe why not you?' And seeing that most of our modern knowledge comes from the rat it may be taken as germane that animals are very fond of offal when Martha (a puppy) kills a rat while Mary appropriately looks on Shadrach and Meshach (the kittens Abednego died untimely) wolf the guts and viscera but they leave the muscle alone unless they are hungry though they will scrunch up the head apparently to get the brain which always used to be a human delicacy at pig killing and may be of some unrealised importance I do not remember ever hearing anything about the nutritive qualities of brain But on the whole practice is without doubt sound and I have no desire to dispute the propriety of having meat and pudding at the same sitting what I should like *to know is the reason for it Is it* something to do with the stimulation of the stomach by meat to secrete gastric juice or is it that the liver likes to have the amino acids and carbohydrates presented to it about the same time or is it merely an illustration of the truth that man does not live by bread alone but needs the right æsthetic circumstances to get the best out of his meals? After all, meals are perhaps meant as much for conversation as for nourishment

* * *

Another custom which causes an enormous amount of work all over the world is the habit of cooking food and there does not seem to be any very complete explanation of why it is done yet the proportion of uncooked food we eat is very small No animal cooks its food and man may have taken to it because he made a fire to warm himself and found that roasting a piece of flesh made it more tasty But the habit is far more widespread than are the climatic conditions which need artificial heat (having just read the directions for writing for THE LANCET I see that I ought to have written cooking is done in hot as well as cold places but let it pass), and man is evidently strongly of opinion that cooked food is better for him than raw or at least that he likes it better indeed anyone who regularly ate raw mutton chops in England nowadays would be looked upon as a disgusting fellow little better than a cannibal Yet man can live on uncooked meat and vegetables raw minced flesh was the mainstay of some therapeutic diet or other and there are quite a number of people who eat raw carrots and even raw cabbages either to keep away cancer or on general hygienic grounds But the habit is certainly to cook one of the great virtues of the seal is that he carries with him the oily fat with which his flesh may be cooked in the Arctic whereas fish do not The general explanation of cooking would probably be that it makes food more digestible This seems true for some vegetables at any rate it is said that one of the troubles of continuous travel at high altitudes as in Tibet is the difficulty of properly cooking rice and the porters get the stomach ache and grow gloomy. The modern canned pea too, being well autoclaved, seems to be easier in the stomach than the freshly boiled little bullets which are often provided. But these matters of the stomach are largely questions of habits and training, and the custom of cooking was evolved by a young and vigorous population whose chief concern was probably to get enough of something. Experiment too is said to show that raw meat is actually digested a good deal more easily than roast or boiled. The whole business seems to need explanation; meanwhile, I hope to go on having well cooked meals. It is possibly a question of de-naturing the proteins; it may be easier (using Huxley's illustration) for man to turn cooked crab into human proteid than for a crab to convert raw sailor. Or perhaps man realised at an early stage what we are only just learning about milk—that it is better to more or less sterilise it. The chances of infected or contaminated food were of course much greater than they are now; the old dame who kept my first school dated from the time when water was pretty dangerous stuff, and when we were heated in innocent play and likely to drink a lot she insisted that it must be first boiled; unfortunately it was warm when it reached us and beastly so, if we could slink off, we drank from a cattle trough in the field.

* * *

Most of the modern work on nutrition has concerned infants and children, perhaps because they are more amenable than grown-ups and less opinionated and, like rats, are prepared to eat what fate and elder people heap upon their plates. The good results are everywhere apparent, and there is no more striking difference between England of to-day and thirty years ago than the appearance of the children, in town and country alike and perhaps particularly in the country, much of which was, and unfortunately some still is, thoroughly slummy. It does not of course all come from better feeding; boots, clothes, and ideals have all changed, and there has been a general increase in the standard of life. But food seems to have a good deal to do with it. What some people have wondered at is whether these larger heavier, rosier children will in the end make healthier men and women and better citizens; to be big is obviously uneconomical unless bigness is correlated with other, more human virtues, and plainly anything comparable to the monstrous rats and guinea pigs which are produced experimentally would be out of place in our society. No clear answer to the question will be available for a long while, and perhaps when the time comes to take stock of what has happened the variables will be confused beyond analysis. No one can define how infantile mortality has been halved more precisely than by saying people began to take notice of it and be ashamed; all sorts of people then did all sorts of things and fatalities soon fell, but it is impossible to measure the credit due to the bacteriologist in the laboratory against that we must give to the kindly woman in the infant welfare centre. We may surmise that there will be the same kind of difficulty when we come to measure food against healthiness. But looking at the young things of to-day it is difficult not to believe that their good food will do much to keep them well, at least in some respects. Bad feeding certainly encourages tuberculosis, though it has no clear relation to the influenza virus or the pneumococcus, and to call any vitamin "anti-infective" seems going rather far. What will happen with the degenerative diseases of middle life is quite unknown and we have no idea whether being 2 in. taller and 7 lb. heavier on leaving school will fend off arterio-sclerosis 30 or 40 years later. However it would be really heart-breaking if we had to think that our nice looking young people are not really healthier than the generation before them.

* * *

This concentration of interest on children has also diverted attention from the far more important group of active experienced men and women between 30 and 50. How are they to feed themselves to get the best out of their brains and training? To say that children are the most important section of the community is sentimental twaddle of the worst kind. They need looking after because they cannot look after themselves, and they are convenient to look after because they can be coerced, but for the well-being of the world the health and liveliness of a man of 40 who has established himself as a good workman at his job is far more important than the state of many children. What are known as "great men" seem to have only one thing in common which is insatiable industry. And what more desirable aim could dietetics have than to enable the middle-aged man to work effectively for 10 hours a day instead of 7, and to avoid fading away towards the end of the afternoon? I do not recall anyone discussing this problem except Dr. Corry Mann, who tried drinking milk with his lunch. Could not the experiment be extended in, for example, Whitehall with some of the surplus milk of which apparently there will still be plenty when the children have had all they ought to? It really looks as if we need something to balance the innumerable organisations for encouraging and improving children—a Society for the Promotion of the Middle Aged or something of that kind.

* * *

Apart from the curious sexual cult of slimming, we hear little in this belly-minded age of the virtues of asceticism, and we are seldom reminded that gluttony was one of the seven deadly sins. Yet there must be something in it. "Up to 20 eat all you can get, from 20 to 40 eat as much as you can, over 40 as little as you can do with," and the mortification of the flesh has never lacked advocates among those who think more of intellectual and spiritual things than of being hearty and jolly, though one may suspect that "more people are killed by overeating than overdrinking" must have come from the bishop who said he would rather see England free than sober. How far it has been universal for saints to subdue the flesh to the spirit I do not know, but a great many of them have done it, in modern as well as ancient times. Unfortunately we know little about the personal habits of distinguished men and their biographies are painfully reticent about such things; some of them have been plump but many have certainly been thin, and not a few of them small as well. What Mr. Gladstone ate for breakfast must surely be as important as what he said in 1881, and in all the charming intimacy of Darwin's "Life and Letters" there is no hint of what he actually did for his queasy stomach. Voluntary starvation for a short time is widely recognised by lay people as a good thing to do when they do not feel very well, and various systems of treatment, orthodox and quackish, have been based on starvation more or less concealed with tasty waters. A friend of mine who starved for a fortnight said that he reached a state of mental clarity (subjective) and exaltation which he would never have thought possible and it was only the sight of his face in a looking glass which sent him in search of food As the best short story in the world tells us Saul fasted before he went to see the witch of Endor and temporary abstinence has been recognised on an enormous scale in a variety of religious cults as a likely precedent to getting authentic tidings of invisible things the consensus of opinion in its favour is overwhelming It might be a good preparation for a difficult consultation or an important experiment Of the bodily and mental effects of habitual austerity we know little Mass experience in times of trouble or in certain social classes is always confused with other factors than diet typhus would have no relation to famine if soap and hot water were to be had for nothing And ascetic individuals who are healthy and productive may well represent the extreme of the normal variation in food requirement. But there does seem a little danger at the present time that the possible virtues of eating less are being overlooked it is established beyond doubt that being too fat is one of the most dangerous diseases anyone can have

CORRESPONDENCE

MANIPULATIVE SURGERY

To the Editor of THE LANCET

SIR,—As one who was present at the demonstration by Sir Herbert Barker at St. Thomas's Hospital on July 22nd 1936 I was interested but not surprised, to learn of the gratifying proportion of successes that resulted and which are recorded and analysed by Mr Bristow in the last issue of THE LANCET After the heated controversies of the past, it was a courteous gesture on the part of Sir Herbert Barker to give this interesting demonstration and I yield to nobody in my appreciation of the pertinacity with which this able exponent of manipulative methods has fought for the recognition of this valuable and highly specialised method of treatment The demonstration and its results have received wide publicity in the lay press and may I without appearing ungenerous utter a plea for a more logical and unbiased attitude towards this important problem and one that does justice to those within the ranks of the medical profession who quite independently and without any knowledge of Sir Herbert Barker's methods although doubtless inspired to a certain extent by his advocacy have striven to place this method of treatment upon a scientific basis?

The impression that the average layman is clearly intended to form from a perusal of many of the reports in the lay press is that the medical profession for a long period has known nothing and cared less about manipulative treatment and that Sir Herbert Barker having generously demonstrated his methods, we should now pursue an active policy and give our patients the benefits of these—i e Sir Herbert's—methods There is a grave fallacy in this familiar argument for are not the methods of medical pioneers in this sphere also worthy of consideration and study?

There must have been few present at the demonstration who did not learn something of real value although some of the methods demonstrated have been practised and taught by orthopædic surgeons for years The results confirm the view held by most of us that no permanent cure of a badly torn semilunar cartilage with recurrent displacement can be brought about by manipulation The marked improvement brought about by manipulation in the cases of recurrent dislocation of the shoulder of long standing is a remarkable fact quite new to most of us and merits careful consideration Speaking personally I saw little to cause me to make any marked alterations in my own technique I have little doubt that Sir Herbert Barker himself deprecates the verdict of some of the sections of the lay press that the work of the medical workers in this field is of such insignificant value that it can be ignored

The pioneer work of the late Sir Robert Jones and of others in this field was also of inestimable value in convincing the medical profession of the value of manipulative methods and there are others still in our midst who have not had the opportunity of seeing the technique of Sir Herbert Barker but who have devoted much time and energy to the advancement of this branch of surgery and who like myself have lectured and given demonstrations to doctors in all parts of the British Isles Mr Bristow in his concluding remarks states

> From Barker's demonstration, certain excellent details in his technique will probably be followed He taught the value of repeated manipulation the value of traction the personal supervision afterwards and above all the splendid optimism which is essentially a part of treatment in helping those with long standing disabilities whose confidence has been rudely shaken by failures of the earlier efforts at cure.

May I in order to do justice to my colleagues and myself parallel each of these main points by quotations from the first edition of my book on Manipulative Surgery published in 1925

> (1) *The value of repeated manipulation*.— In difficult cases, it is a sound principle to stay one's hand and be content with achieving the desired result by a carefully planned series of manipulations rather than to run the risk of exciting severe reaction and shock (p 30)
>
> (2) The *value of traction* is duly emphasised in [illegible] sections of the book devoted to manipulation of individual joints. For instance on p 129 in [illegible] the wrist the advice is given that "During these movements traction should as far as possible be [illegible]"
>
> (3) *Personal supervision after manipulation*.—"[illegible] sation and personal attention to the smaller [illegible] essential (p 30)
>
> (4) *The importance of restoring the patient's* [illegible] — The importance of firm but kindly [illegible] and [illegible] inspiring confidence and keen co-operation [illegible] can hardly be over-estimated (p [illegible]) "The medical man must never forget that [illegible] have previously consulted divers others [illegible] and unqualified and that their [illegible] upon him He must prove [illegible] and by a judicious combination of [illegible] and determination snatch victory often [illegible]" (p 32)

This evidence is merely [illegible] to show that the elements of Sir Herbert Barker's [illegible] which Mr Bristow very [illegible] worthy of special note [illegible] independently [illegible] of his colleagues Similar [illegible] obtained from the teaching of [illegible] surgeons

I am [illegible]

[illegible] FISHER

Montague-street [illegible]

To the Editor of THE LANCET

SIR,—I [illegible] at ness to Sir [illegible] this be [illegible] able [illegible] he treated by manipulation at St Thomas's Hospital on July 22nd, 1936 Case 1 was said to be a case of recurrent dislocation of the shoulder of 15 years' duration The shoulder had "dislocated" hundreds of times, sometimes daily It had never had to be reduced by a doctor

I described the pathology of recurrent dislocation of the shoulder, I believe for the first time, in 1923 (*Brit med J* 2, 1132) The condition is due to a wide traumatic separation of the fibrocartilaginous glenoid ligament from the anterior margin of the glenoid cavity The defect is permanent, because there is no tendency for the torn ligament to reattach itself to the bone The head of the humerus is therefore free to leave the joint anteriorly on the slightest provocation The anatomical condition is quite constant and can be seen and verified by any surgeon who cares to expose the anterior margin of the glenoid cavity in a genuine case of recurrent dislocation of the shoulder It is then obvious that the only rational treatment is to reattach the glenoid ligament (or the capsule) to the bone from which it has been torn This operation never fails

With regard to Case 1 (above), I have yet to meet the man who could reduce a dislocation of his own shoulder joint, and it would be interesting to know precisely what happened on the hundreds of occasions when this shoulder was alleged to have been dislocated When Barker examined the man he said, "It is obvious that there is no large defect in the capsule in this case"—a statement which I would suggest is a contradiction of his diagnosis, since dislocation of the head of the humerus cannot occur without such a defect In conversation I once asked Barker how he accounted for his success in view of what we know about the pathology of recurrent dislocation He replied frankly that he did not know, but he could only suppose that his manipulation caused such a stirring up of the tissues that the dislocation was prevented If this is the true explanation, it must surely be unique in Barker's experience (as in ours), for in no other region of the body is manipulation designed to produce *limitation* of movement, indeed it is difficult to see how it could do so Moreover, nothing that Barker did to this man (Case 1) in our presence could possibly have produced such a violent reaction as is suggested by this explanation

Recurrent dislocation of the shoulder joint is not very common I think it is quite clear that the condition which Barker calls "recurrent dislocation of the shoulder" is not the same as that which we call by that name It is more than doubtful whether the man here referred to (Case 1) ever dislocated his shoulder That he felt something "slip" in his shoulder joint I do not doubt, and that this "slipping" was due to adhesions or contracture in or about the posterior part of the capsule of the joint is more than likely We are familiar with such cases, and incidentally we have treated them by manipulation, but we do not call them cases of recurrent dislocation of the shoulder At the same time we must admit that recurrent dislocation of the shoulder has been apparently cured by the most irrational surgical procedures, and, if it can be cured by manipulation, we are only too willing to learn But it is fair to demand that the diagnosis should be unequivocal, and it is not unreasonable to ask for an intelligible explanation.

I am, Sir, yours faithfully,
A S BLUNDELL BANKART

London W March 1st

PROTAMINE INSULIN (WITH ZINC)—SUSPENSION

To the Editor of THE LANCET

SIR,—The retarding action of protamine, with the addition of zinc, on insulin has been the subject of investigation for some time past Protamine Insulin (with Zinc)—Suspension is now made available by the four firms associated with the manufacture of insulin in this country, Messrs Allen & Hanburys Ltd, Boots Pure Drug Co Ltd, The British Drug Houses Ltd and Burroughs Wellcome & Co

The preparation is a suspension of insulin with added protamine and zinc, of such a character that it is readily and evenly diffused on shaking prior to administration As it is more slowly absorbed than unmodified insulin it should be of particular use in cases where unmodified insulin does not provide adequate control or where several administrations daily are necessary While extensive clinical trial has determined the issue of a satisfactory preparation, there is still much to be learned about its general use, therefore care will be necessary if reactions are to be avoided due to unfamiliarity with its use or deviations from a properly balanced dietary

Protamine Insulin (with Zinc)—Suspension is issued, at present, in one potency (40 units per c cm) Two sizes are available 5 c cm containing 200 units and 10 c cm. containing 400 units The packings will be distinct in colour from existing packings of unmodified insulin

We are, Sir, yours faithfully,
ALLEN & HANBURYS LTD,
BOOTS PURE DRUG CO LTD,
THE BRITISH DRUG HOUSES LTD,
BURROUGHS WELLCOME & CO

London March 1st

TREATMENT OF FRACTURE OF THE NECK OF THE FEMUR

To the Editor of THE LANCET

SIR,—Mr Bailey seems to have missed the point of my previous letter I contend that radiological control is *the* essential part of the technique of extra articular nailing Instruments to place the guide may be classified as luxuries

The many advantages of this new surgical technique that can successfully replace a large exposure of the hip are obvious I criticised Mr Bailey's technique because he contended that his instrument replaced close radiological control I remind Mr Bailey that I agreed that skeletal traction *sometimes* reduces, with accuracy, a medial fracture of the femoral neck, but the large majority of these fractures are not so reduced I contended that X rays were wanted first to control the manipulations necessary to obtain accurate reduction in this larger group, and next to confirm the accuracy of the reduction Now, an instrument can place a guide wire with accuracy In common with Mr Bailey I use one that enables me to do this Its advantages are a speeding up of the operation and a decrease in the number of necessary radiograms, but I think that is all we can expect of it

Recently Böhler and Felsenreich (who together have nailed nearly 200 necks) have shown me the complications that can occur during this operation, and I remain quite convinced that the steps of it need the closest "watching" With regard to the complication I instanced in my previous letter I have watched the oncoming nail displace an accurately reduced head from its position on the neck on three occasions in my small series of 28 radiologically controlled operations in spite of the guide wire being in the head fragment. I now transfix small head fragments to the pelvis with a stout guide wire and they are not displaced. This is but one example of planning to circumvent complications as they arise and are seen in the radiologically controlled operation. A Thomas ring around the upper thigh and the patient in bed gives the radiologist little help in his important work, for the films must be of the clearest definition if they are to be of value.

The success of this operation will be judged on its end results and I believe the end results will justify the ordeal of an operation on an orthopædic table under close radiological control.

I am, Sir, yours faithfully,
WILLIAM GISSANE.
St. James' Hospital, S.W., Feb. 28th.

OXYGEN ADMINISTRATION

To the Editor of THE LANCET

SIR,—Recently a box mask was introduced for cheap and efficient administration of oxygen. The mask described previously was for adults (14 years or older). Inquiries having been made as to the application of the mask to younger patients, details are given in the Table below for the correct dimensions of the mask for various ages and also the approximate rates for flow of oxygen for ordinary conditions of pneumonic anoxæmia. Higher rates may be tried if necessary. These rates have been worked out from the tidal air for various ages. The mask may be cut from a suitable light cardboard box and a light rubber tube (internal diameter 5 mm.) in about 10 minutes, following closely the details given in the previous publications (*Brit. med. J.* 1936, 1, 1246 and *Lancet* 1937, 1, 82).

Dimensions of Mask and Rates of Oxygen Flow for Various Ages

Age	Weight in kg.	Tidal air (c.cm.)	Dimensions of mask (cm.)				Rate of oxygen flow litres per minute
			Length	Breadth	Depth	Volume	
0–6 months	3–7	48	6	5	3.5	105	0.7–1
6–18 „	7–12	[illegible]	8	6	4	192	1–2
3–7 years	14.3–19	121–[illegible]	1[illegible]	9	4	132	–3
8–14 „	22–20	221–395	13	10	5	6[illegible]0	3–4
14 years and over (adult)	60–70	140–5[illegible]0	15	12	7	1 [illegible]60	5–6

The efficiency of the mask depends on the inlet tube being turned back on itself and placed in the correct position inside the mask so that the incoming oxygen strikes the middle of the top of the inside of the mask. The opening at the back of the mask to accommodate the nose, mouth and part of the chin must be cut to suit the size of the face of the patient. The mask must be connected with a "Bobbin" flow meter and automatic regulator for the oxygen cylinder as shown in the previous papers mentioned above.

The masks may be made also from aluminium or from a wire frame and a linen or silk covering (makers Siebe Gorman and Co., London, S.E. 1).

I am, Sir, yours faithfully,
London, N.W., Feb. [illegible]th. J. ARGYLL CAMPBELL.

BASOPHIL PITUITARY CARCINOMA

To the Editor of THE LANCET

SIR,—In the annotation in your issue of Feb. 20th upon our case of Cushing's syndrome associated with a basophil carcinoma of the anterior lobe of the pituitary you refer to Crooke's work upon the hyaline change in the cells of the gland in this syndrome, a change which he holds to be characteristic of the condition, whether associated with pituitary, adrenal or thymic tumour. You justly state that our failure to find such change in the malignant cells of the pituitary neoplasm is in no way a refutation of Crooke's views. Since the publication of our article in *Brain* we have satisfied ourselves—and we would gratefully acknowledge our thanks to Dr. Crooke, who has examined some of our material and allowed us access to certain of his preparations—that the surviving basophil cells of the pituitary gland itself which were present in the pars intermedia do in fact show the hyalinisation which he has described.

We are, Sir, yours faithfully,
HENRY COHEN.
J. HILARY DIBLE.
The University, Liverpool, Feb. 24th.

ARTIFICIAL PNEUMOTHORAX ON STATISTICAL TRIAL

To the Editor of THE LANCET

SIR,—I should like to support Dr. Andrew Morland's admirable comments in your issue of Feb. 20th on the result of the recent statistical inquiry into artificial pneumothorax treatment in England. Should another statistical investigation be made in a few years' time I believe the outcome will be very definitely in favour of artificial pneumothorax. Among factors likely to influence favourably such figures are:—

(1) The greater tendency to adopt the treatment in earlier cases.

(2) The more frequent use of thoracoscopy for the division of adhesions.

(3) Paralysis of the diaphragm towards the termination of pneumothorax treatment in selected cases.

(4) Though possibly to a smaller extent, the less conservative attitude to the adoption of bilateral artificial pneumothorax in a larger number of suitable patients.

(5) Indirectly, an improvement in radiological equipment permitting of a more accurate control.

I am, Sir, yours faithfully,
Montana, Switzerland, Feb. 27th. HILARY ROCHE.

HORMONE TREATMENT OF UNDESCENDED TESTIS

To the Editor of THE LANCET

SIR,—The article by Mr. Mimpriss in your last issue raises some important points in regard to the use of gonadotropic hormones in cases of undescended testes. His experience leads him to believe that there are contra-indications to this treatment and many would agree with him here. He now brings forward a new indication for treatment: bilateral cases with subnormal genital development. He records this subnormal state in 9 of his 20 cases with ages from six to thirteen years—although we could exclude case No. 8 on the ground that microgenitalia is a normal feature of the Fröhlich type and is corrected later. If we are to adopt this new indication it will be necessary for us to have a very clear idea as to the normal size of the genitals at different ages. Have we adequate knowledge of this matter? I doubt it, and remarked on the variatio size of these organs in normal boys in your columns (1936, 2 929) I would say in fact that the size of the genitals is one of the most variable features in boys up to full puberty, and would urge that this new indication be not yet adopted as a satisfactory one

I am, Sir, yours faithfully,
PEARSE WILLIAMS

Harley street W Feb 28th

To the Editor of THE LANCET

SIR,—Mr Mimpriss was, we feel, unlucky in inducing descent in only 6 of his 20 cases, and perhaps if he had had better results he would be less seriously impressed with the genital hypertrophy which occurred in 19 of them This complication has been encountered by most of those who have used this form of treatment In our own series of 29 cases successful descent was achieved in 23, and genital hypertrophy was noted in 15 out of 26, but the enlargement of the testes was always one of our objects, and the enlargement of the penis has never struck us as being so undesirable as to cause us to abandon the treatment as Mr Mimpriss did. Nor do we agree with him that hormone therapy should be confined to bilateral cases with subnormal genital development only, for we have found it frequently successful in cases of unilateral failure in descent, sometimes associated with apparently normal genital development

We suggest that the points to be considered in connexion with this form of treatment are —

(1) *The optimum age at which treatment should be instituted* —Spermatogenesis normally begins at the age of 9 and and the longer it is delayed as the result of the ectopic position of the testis the less likely it is to occur should this position be subsequently corrected This is our answer to the statement that 90 per cent of testes descend spontaneously by the age of 16, and that therefore no treatment should be instituted before that age Treatment before the age of 9 may lead to undesirable complications, such as the onset of precocious puberty and the premature awakening of the sexual appetite

(2) *The selection of cases for hormone therapy* —It has been repeatedly pointed out that in cases in which there is some mechanical barrier to normal descent, such as an overlying scar of a previous unsuccessful operation for orchidopexy, hormone therapy is very unlikely to be effective Furthermore, as Spence and Scowen[1] have said failure is probable if the testis is in the abdominal cavity and does not engage at the internal inguinal ring The inevitability of future surgical interference as in those cases associated with a hernia, might conceivably be regarded as a contra indication to hormone therapy on the ground that the ectopic testis can be dealt with at the same time as the repair of the hernia It is, however, a fact that gonadotropic influences may increase the mobility, if not actually lower the position, of the canal dwelling testis, and thereby render orchidopexy less reminiscent of a tug of war Furthermore, as pointed out by McLellan,[2] who advocates both pre and post operative treatment, the testis transferred to the scrotum by orchidopexy may fail to develop in its new surroundings unless encouraged to do so by hormone administration

(3) *The possibility of permanent functional damage to the testis by the use of gonadotropic hormones* —This is referred to by Mr Mimpriss in his paper and darkly hinted at by Cabot[3] The facts are these as the result of continuous administration of gonadotropic extracts, antigonadotropic factors are elaborated in the patient's blood stream which may, if allowed to circulate for a sufficient period, affect the testis adversely but only temporarily As soon as these antigonadotropic substances disappear, as they do when gonadotropic administration is discontinued, the testis rapidly recovers its functional activity In order to avoid this complication treatment should be administered (as Spence and Scowen recommend) in a series of courses separated by intervals of a month or so during which no injections are given

In our opinion no serious contra indication to gonadotropic therapy in undescended testes has yet been brought to light, and we believe that no *harm* can be done if it is applied to any type of case If, however, one is aiming, as one should be, at a high proportion of successful results, a careful selection of cases should be undertaken on the lines outlined above —We are, Sir, yours faithfully,

UNIVERSITY OF LONDON MEDICAL GRADUATES SOCIETY

To the Editor of THE LANCET

SIR,—The University of London and its graduates are entering into a new heritage as their great building rises in Bloomsbury, for it will create a centre of university life such as London has long desired The future however will be made by man and not by stones, for the traditional spirit of great centres of learning is created by the men who move in them Our university has yet to develop its traditions in the fullest sense, for hitherto the graduates have had few associations with their university except as an examining body, and among the medical graduates the loyalties of professional life are given chiefly to their own medical schools This has led, in the past, to a narrowing of outlook, and has been a hindrance to progress Lister was a London surgeon, yet London was almost the last of the great centres of medical work to acknowledge the truth of his teaching He himself attributed this to the lack of a university and of the university spirit, which, valuing the search for truth above all else, subordinates to it all considerations of personal advantage

London can never enjoy a university life as intimate as that which exists in smaller towns, but, with the coöperation of its graduates, it has now an opportunity of developing a university spirit and tradition along its own lines

Nine years ago, the University of London Medical Graduates Society was formed to provide a social meeting ground and bring all graduates of the medical faculty of the University into touch with one another The University has recently granted official recognition to the Society, and the annual dinner on May 6th next will be held for the first time in the university banqueting hall. The vice chancellor has signified his intention of attending the dinner, and it is hoped that the occasion will arouse the interest of medical graduates in their university and that many who are not yet members will join Overseas graduates, who may be in London for the Coronation celebrations, will be specially welcome Guests, medical or non medical, may be invited by members

The objects of the Society are, in brief (*a*) to bring medical graduates of the University of London into closer relationship with their university and with one another, (*b*) to keep in touch with "overseas" medical graduates of the University, and (*c*) to promote the interests of the university and its medical graduates The Society has no political activities There is an annual dinner in London during May, and dinners are held in other centres from time to time, whilst an afternoon reception and visits to places of interest take place during the spring

OXYGEN TENTS

To the Editor of THE LANCET

SIR—A statement appeared in the *Times* of March 2nd in connexion with a private venture ambitiously styled the National Oxygen Tent Service The statement is made that the formation of the service was in furtherance of a movement initiated by the British Red Cross Society Work in this country on the oxygen tent was being carried out and an oxygen tent service was in existence long before the Red Cross made tents for the twelve hospitals and they did so as the result of a letter signed by physicians and surgeons on the staffs of those hospitals asking for their help Hence the Red Cross did not initiate any movement moreover they decided they would not themselves undertake an oxygen tent hire service and I am informed that they are not sponsoring this particular venture

As for the so called open top tent itself we are still awaiting published results in this country I doubt whether in general it would be as effective as Dr Argyll Campbell s much simpler face mask

I am Sir yours faithfully

London, W March 2nd   E P POULTON

MENTAL DISORDER AND ENDOCRINE ACTIVITIES

To the Editor of THE LANCET

SIR—With reference to the leading article on this subject in your last issue may I suggest that the most important contribution of endocrinology to psychiatry will prove to be in the field of psychodynamics It is now generally recognised that our mental energy is derived from instinctive tendencies or drives, and since we share many of these instincts with the lower animals their endocrine relationships should be susceptible to investigation by means of laboratory experiment This particularly applies to Freud s libido which plays such a prominent part in modern psychopathology Recent discoveries in endocrinology have thrown a flood of light on the physiology of sex and it should not be difficult to apply this knowledge with a view to elucidating the glandular factors which contribute towards sex drive Biochemists are naturally preoccupied in investigating the action of the various hormones on bodily processes and the claims of psychiatry are liable to be overlooked Experiments dealing with the organic basis of libido could be performed most profitably by those who have had a psychological training but I know from personal experience that it is practically impossible for a man who is working in a mental hospital to obtain financial aid for research of this nature Nevertheless the work should be done by someone—I am Sir yours faithfully

RITUAL PURGATION

To the Editor of THE LANCET

SIR,—May I suggest that there are two sections of the community who should be protected from the devotees of these rites?

(1) Inmates of nursing homes are given large doses of castor oil often on the orders of a nurse regardless of any protest on their part that it either upsets them or that the bowels have already acted that day

(2) Thousands of young children are submitted to the same ritual every Saturday night (whether they need it or not) with the result that Sunday is spent by them in working it off

Is it advisable to add oleum ricini to the list of dangerous drugs?—I am Sir yours faithfully

STELLA CHURCHILL.

Cumberland terrace N W March 1st

To the Editor of THE LANCET

SIR,—If the administration of a purgative be one cause of disturbed bowel habit may I suggest another cause? I refer to the time-honoured system of giving hospital patients their breakfast at 5 30 or 6 A.M The after breakfast call comes not at an established hour of the morning but at a variable number of minutes after the first cup of tea Unfortunately at such a time the night nurse is to be seen distractedly rushing round clearing away trays making beds taking temperatures writing up report &c and it is a brave and heartless patient who has the courage to call for a bed pan This may be moral cowardice or it may be noble sufferance but it happens Nor may the patient be relieved at 8 A.M when the day staff come on (if indeed he has any urge left by this time) for the first half hour or so is taken up by the ceremony of report.

The remedy is simple Let the last duty of the night nurse be the giving of breakfasts at 7 30 A.M and the first duty of the day nurses be the distribution of bed pans at 8 A.M There seems to be the choice between the rhythm of hospital routine and the rhythm of the sphincters

I am Sir yours faithfully

PANEL AND CONTRACT PRACTICE

The Drug Bill

LANCASHIRE is well known as a "peak" area in respect of the increasing cost of providing medicines for the insured population The report of the panel committee following investigation of the prescribing of a Lancashire doctor for the first quarter of 1936 shows a total cost of £157 9*s* as against an average for the same number of persons in the area of £106 0*s* 4*d* The difference of over £50 was attributed mostly to the number of prescriptions but partly to the high cost of ingredients

Dr X had prescribed during the quarter for 42 80 per cent of his total list as against an average percentage, based on figures for three years on a large sample of cases, of 37 12 per cent He had issued 4 821 prescriptions per person prescribed for, as compared with a calculated expectancy of 3 71 The relevant figures from four local comparable practices were 37 44 per cent and 3 902 prescriptions As to the cost, the average proportion of prescriptions in England ordering proprietary preparations is just over 1 per cent, costing 4 5 per cent of the whole Dr X's proprietaries averaged 5 8 per cent, and their cost 19 4 per cent of his total prescription cost Dr X was unable to offer an explanation with regard to his number of prescriptions He did not practise in a particularly poor district where there was an unusual amount of unemployment, he maintained that all the patients prescribed for needed attention, and that no unnecessary prescriptions had been issued

The panel committee found some difficulty in estimating the amount of excess, owing to lack of precise evidence The total cost of proprietaries was £14 2*s* 5*d*, and while it was agreed that often there was no actual equivalent, it was submitted that other formulæ could be used with a similar therapeutic effect About £5 might have been saved by the use of non proprietary articles Greater difficulty was experienced in estimating the excess due to "undue frequency," but the fact that many scripts contained two or more prescriptions (3367 scripts = 4233 prescriptions) was held to have some bearing on the matter

The panel committee considered that in a list of over 2000 most consultations would probably be in respect of slight ailments, for which the appropriate remedy would cost little Few of the samples of the scripts examined were found to cost less than the average cost of a prescription issued in the area Very little use appeared to have been made of the National Formulary

The insurance committee decided, subject to there being no appeal by the practitioner, to make representations for the withholding of £40, which was the amount suggested by the panel committee as the minimum imposed on the Drug Fund in excess of what was reasonably necessary

A Satisfactory Compromise

The medical service subcommittee is often reviled and it is well to record a hearing with an ultimate result satisfactory to both parties An insured person was taken ill while on a visit at an address outside the area of the practice of his insurance practitioner The relatives did not know he was an insured person and called in a local practitioner, who gave the patient the option of treatment in hospital or in a nursing home The patient chose the nursing home and was treated there by the practitioner At some time during his stay the patient asked the practitioner whether he was "on the panel," but did not say he was insured nor asked to be treated as an insured person Private certificates were issued, and in due course an account amounting to £11 16*s* was rendered. The insured person told the subcommittee that he was under the impression that the fees for the nursing home were inclusive of medical attendance, and he felt that the account rendered by the practitioner was somewhat excessive The practitioner said that he was under the impression throughout that he was treating a private patient, and added that if the patient had told him that he found difficulty in paying his account he would have been prepared to adjust it The practitioner voluntarily offered in the circumstances to accept £4 in settlement of his account, and this was willingly paid. The subcommittee in their report note their view that the practitioner made a generous offer, and their satisfaction that the question had been adjusted amicably without any recommendation from them

"Outside the Scope"

Among the (round) 2000 practitioners on the London panel only 22 charged, or contemplated charging, insured persons fees during the year 1936 for treatment outside the scope of medical benefit, but rendered by them owing to their special experience in that class of work. The number of cases notified was 110 and in every case the relevant committees agreed that the practitioners concerned were possessed of the necessary skill and experience to enable them adequately to carry out such services Sixty two cases referred to ophthalmic services—but it should be remembered that notifications are required only when the practitioner renders such a service for one of his own insured patients—24 related to treatment by ultra violet rays, 4 were psychotherapy for anxiety neurosis Most of the remaining 20 were in respect of surgical services, 1 was an X ray for suspected Pott's fracture, and 1 was the administration of an anæsthetic for tonsillectomy by dissection When the operation is outside the contract and is performed by a second doctor, the anæsthetic being given by the insured person's own doctor, no fee is chargeable either to the practitioners' fund or to the patient—unless, as in this case, the giving of the anæsthetic is itself a specialist service

---

LINCOLN COUNTY HOSPITAL —This hospital received the record income of £23,953 last year an increase of over £2000 on the previous year The extensions fund now stands at £50,500 and the overdraft is reduced to £5500

The following courses are available for M R C P candidates heart and lung diseases at the Royal Chest Hospital (on Mondays, Wednesdays, and Fridays March 1st to 19th) neurology, West End Hospital for Nervous Diseases (afternoons, March 8th to 19th) A demonstration on pulmonary tuberculosis will be held at Preston Hall on April 3rd A mock trial of a motorist accused of being under the influence of alcohol will be held on Thursday, March 11th at 8 30 P M Admission will be by ticket only Full details of the trial, and of all courses, can be had from the secretary of the fellowship, 1, Wimpole street, W

OBITUARY

SIR HENRY JACKSON Bt M B Edin , B Sc Lond

As was announced briefly last week Sir Henry Jackson the well known authority on transport and traffic questions died suddenly on Feb 24th. He collapsed at the dinner of the Wandsworth branch of the London Association of Local Government Officers and died immediately at the Bolingbroke Hospital to which he was taken after the seizure

Henry Jackson was born at Heywood, Lancashire in 1875 He received his education at the Bury grammar school and proceeded to Cambridge where he obtained a first class in the natural sciences tripos in both the first and second parts, in the interval taking the degree of B Sc at the University of London He was elected a fellow of Downing College Cambridge where he was a science lecturer and was for ten years tutor While at Cambridge he became a Fellow of the Cambridge Philosophical Society and contributed papers also to the Royal Society and the Chemical Society At this point he relinquished his academic career in response to a call to play a fuller part in social activities He graduated as M.B Ch.B in the University of Edinburgh and went into general practice in Putney where he soon became a marked man both for professional capacity and his interest in municipal affairs During the war he served in the R.A M C with the rank of major and at the conclusion of hostilities returned to his medical practice In 1921 he was elected Mayor of Wandsworth He held this municipal post for three years, and in 1924 was elected Member of Parliament for Wandsworth. He sat as a conservative but with the greatest interest in the welfare of those whose position submitted them to a life of struggles He held the seat for five years losing it in 1929 when his defeat at the poll caused some surprise ; but he regained the seat two years later his popular claims being unexceptionable In 1935 he was re elected and was representing the borough at the time of his death. By this time he had established a high position in the House, as a committee man and as one to whom municipal life and especially the increasing difficulties presented in the conduct of urban traffic made a particular appeal. Throughout all the latter part of his parliamentary career he was recognised as an authority on traffic problems the subject upon which most of his contributions to debate were directed. He was appointed chairman of the London and Home Counties Traffic Advisory Committee and became chairman of the special subcommittee which considered the question of the new bridge at Charing Cross The subcommittee was formed at the instance of the Ministry of Transport and Jackson s selection to preside over its counsels was approved by all his colleagues in the House

[Photograph by Elliott & Fry

SIR HENRY JACKSON

He was never regarded as a party man, although he was chairman of the Conservative London Members Committee nor as a medical man although he presided over the Medical Committee of the House His medical knowledge was displayed by the part which he played in debates affecting many sides of the municipal life and the status of municipal officials and the practical dealing with questions where public health and official administration came into contact made a close appeal to him Before his other duties became so pressing he was an active member of the London Voluntary Hospitals Committee and sometimes occupied the chair at its meetings

Through his many relationships in public life in his parliamentary constituency and within the House of Commons Jackson established a fine reputation as a man of affairs He was sound industrious and kind and was assisted in all the work which he undertook by his bluff and equable personality His death when there might well have been expected for him a considerable extension of time in which to see the fruits of his labours is a source of wide grief to a large circle of fellow workers and friends

He married in 1904 Edith Margaret Smalley of Norton Grange Castleton Lincs who survives him, but there were no children of the marriage He was knighted in 1924, the year in which he commenced his Parliamentary career and was created a Baronet in 1935 He was 61 years of age

THOMAS MARTIN CORKER C.B M D R U.I

The death occurred in London at the age of 80 on Feb 24th of Major General Thomas Martin Corker a distinguished member of the R.A.M.C He was born in Co Cork the son of the late T W Corker He studied medicine for four years at Queen s College, Cork, where he was a gold medallist and senior scholar taking degrees in science with first class honours and distinguishing himself as an athlete. He then turned to medicine and entered St Bartholomew's where he again established himself in the forefront of both scholastic and athletic worlds To quote his own words while working at Bart s I was still applying for divers chairs—in natural history geology botany For these he obtained excellent testimonials from his teachers but having graduated M D at Queen s College Cork in 1879 he joined the R.A.M.C which he served for 38 years the greater part being spent in the East He was on the North West Frontier in the Khyber Pass in 1880–81 and again during the serious outbreaks of 1897–98 against the Mohmands and in the Tirah campaign against the Afridis In the latter he took part in the battles for the passes of Sampagha and Arhanga and in the four days march in intense cold down the Bara valley the worst part of the campaign For this he was mentioned in despatches and received two clasps for his medal. Promoted a colonel in 1905 he became principal medical officer successively to the commands in Scotland Egypt and Cape Colony He returned to India in 1911 on becoming a surgeon general and was D D M S first of the Lucknow division and subsequently of those in Poona and in Secunderabad He was honorary physician to the King from 1912 to 1918 He made his mark during the years of the late war where he did administrative work of great responsibility, and for his services he was created C B and a Knight of St John of Jerusalem He retired in 1918, and two years later his university honoured him with the degree of LL D

Major General Corker had a ready pen which he used to the best advantage both in respect of his military work and in more popular spheres For example, he published articles in *The Cricketer*, and three years ago reminiscences of his student days in the *St Bartholomew's Hospital Journal* In the daily press he occasionally wrote vigorously on political matters, and particularly about the recent changes in India Latterly he was often to be seen at his old hospital where he showed great interest both in present problems of medical education and in the students' activities He will be remembered for his reliability—the key to the success of his career—and for his effervescent good humour

General Corker leaves a widow, Florence, the daughter of J E Leslie of Passage West, Co Cork

FREDERICK RANSOM, M.D Edin

Dr F P F Ransom, who died on Feb 23rd at the age of 87, qualified M R C S Eng in 1871 and became M.D Edin in 1875 His chief interest was pharmacology and it was this subject he studied abroad in Berlin and then in Halle and Marburg, working for a period as assistant to von Behring and Hans Meyer In 1910 Dr Ransom was elected to a Beit fellowship, and worked at Cambridge, with W E Dixon, on the action of caffeine and theobromine From 1912 to 1924 he held a readership and subsequently a chair in the University of London at the London (R F H) School of Medicine for Women, where he established the department of pharmacology He was one of the earliest teachers to recognise the importance of providing a course of experimental instruction for students, and he thus succeeded in stimulating their interest in a subject which had till then been studied in a rather perfunctory way His personal work was largely concerned with tetanus and diphtheritic paralysis, and with the mechanism of immunity He was a wide reader as well as an enthusiastic research worker His knowledge was readily placed at the disposal of colleagues and students, and he spared neither time nor energy in their service All those who have ever worked with or under him will remember with gratitude his helpfulness and his kindly, modest, and courteous personality

Dr Ransom's last years were spent in retirement in the country he loved, where in spite of failing eyesight, he followed with keen interest the trend of modern pharmacological research.

ALEXANDER MANUEL, M B , B S , M.R C P Lond

Dr Alexander Manuel, who died suddenly in Mexico City on Feb 22nd, was not often seen in London of late years, but his death will be a source of grief to many friends Of Greek extraction, he was a son of the late Mr M. B Manuel, of Marlborough Gate, Hyde Park, was born in 1878, and educated at Winchester and St George's Hospital. He obtained the English double diplomas in 1905 , in 1907 he proceeded to the M B , B S Lond , and in the following year took the M.R C P Lond After qualification he worked at the Victoria Hospital for Children before becoming house physician at St George's He was elected physician to the French Hospital and to the Hampstead General Hospital, as well as to the Victoria Hospital for Children During the war he served overseas, but his health broke down and he was never able to return to London practice After the war he lived abroad, and practised during the season in Bordighera, where he had a lovely villa, and at Monte Carlo

We owe the following note to a personal friend of long standing, a fellow Wykehamist

"At the start of his career Alec Manuel was possessed of ample private means , it was not necessary for him to work for his living, and it speaks for his strength of character and interest in his profession that he should have devoted as much time to hospital work as he did

"Always most generous in disposition, of late years, in spite of financial losses, he remained the same cheery soul that he always had been He had travelled much, was full of interesting information, and was a most versatile man, and in student days was a great chess player I knew him from school days, and when last I met him he was full of reminiscences , I shall always remember his joyous chuckle as he recounted some difference of opinion he had with his form master over a point in the Iliad, and the next moment spoke of his experiences with the ground ash at the hands of a prefect " R R J

NOEL CHARLES BEAUMONT, M R C S Eng

Dr N C Beaumont, who died on Feb 21st at his house in Stainland, near Halifax, had been district medical officer for Stainland for over a quarter of a century He received his medical education at St Bartholomew's Hospital and took the English double qualifications in 1901 He held resident appointments as surgeon and anæsthetist at the Royal Bournemouth Hospital, after which he proceeded to Port Moresby, Papua, as chief government medical officer On return to England he went into practice in Stainland and was appointed medical officer to the local authority As general practitioner and as official he did excellent work supporting the social organisations of the community, while he showed particular interest in questions of industrial medicine as they arose in the neighbouring factories He was 63 years of age at the time of his death

JOHN HOMER MILLER, M B , Ch B Glasg

THE death is announced at the age of 42 of Dr John Homer Miller who had a fine war record Born at Craigwen, Pontypridd, he received his medical education at Cardiff and the University of Glasgow Previous to qualification he joined as a private the Cameron Highlanders, and received a commission in the Manchester Regiment while serving in France, he was awarded the M C with bar and also obtained the Italian medal for valour At the close of hostilities he entered the University of Glasgow as a medical student and graduated as M B , Ch B in 1922 He then acted as medical officer to the Anglo Persian Oil Company, and was absent from this country in Persia for three years On his return he was attached to the staff at Glanely Hospital, and at the time of his death was senior resident medical officer at the Heathfield Hospital, Ayr, where he was in charge of the tuberculosis wards

PARLIAMENTARY INTELLIGENCE

XCHEQUER GRANTS AND LOCAL HEALTH SERVICES

In the House of Commons on Feb 24th Sir KINGSLEY WOOD, Minister of Health moved the econd reading of the Local Government (Financial Provisions) Bill. He said that this was the first time hat the House had been enabled to consider the grants made under the Local Government Act of 1920 t had been a successful measure whose repeal no party n the State would advocate to-day for none wished o revert to the old percentage system which had been illogical and often unjust The block grant with its famous and ingenious formula took account of the principal factors which governed the need of a locality and through the 1929 Act local authorities had been given much greater freedom in their administration. since 1929 the services of local authorities had reached a much higher standard. There had been for instance a great development in rural sewerage and water schemes and the total expenditure on maternity and child welfare in England and Wales had risen by no less than 25 per cent in the period 1929–35 and on all services by 0 per cent Already in a considerable number of areas the Exchequer met 55–65 per cent of the local expenditure and in the whole country 44 0 per cent But Exchequer subsidies could not go beyond a certain limit without the imposition of some direct control thus sapping the local government institutions and in some areas ending them altogether

Since 1920 however there had been considerable movements of population a decline in the birth rate a quinquennial revaluation a revival of industry in many areas and continued depression in others After long and close discussion with the authorities therefore, the proposals in this Bill had been framed. Summing up its ten main proposals Sir Kingsley Wood said that the Bill provided for the following (1) an increase in the general Exchequer contribution to local authorities of £2,250 000 more than at present; (2) a minimum proportion in the future of 22½ per cent (3) a further relief to local authorities by wiping out expenditure amounting to £2 750 000 (4) a modification of the formula so that grants should be allocated with particular help to those areas that needed it most (5) a favourable basis for the local authorities in calculating weighted population' for estimating the additional Exchequer grants (0) a mitigation of the effect of the fall in this weighted population by increasing the cost of the grants to the Exchequer by another £150 000 and this would also be effected without reducing standard sums on account of the merging of the unemployment contributions, producing another £150,000 for the local authorities (7) a revised provision for the prospective losses of special and parish rates, so that county councils might be enabled to make further contributions; (8) a further provision partly at the cost of the Exchequer to meet cases of difficulty among separately rated losing areas (0) provision for London so that further relief might be given to the poorer boroughs; and (10) a complete investigation of the working of the new formula and of internal distribution in good time before the whole of the block grant had been distributed on the basis of the formula alone

Mr ARTHUR GREENWOOD said that he did not believe the revised formula would work more justly than its predecessor The real trouble of the local authorities was the restriction of their resources. The poorer they were the heavier was the rate burden for a given standard of service but it was just in these poorer towns that the social services were most needed and he went on to quote statistics from the distressed areas showing the small proportion of children in these areas that received free milk or meals. He asked the Minister of Health to review the state of local authorities in the light of modern conditions and consider whether there were not certain services which ought now to be made national or regional responsibilities Secondly the whole basis of the financial relations between the State and the local authorities ought to be reviewed with a new partnership between the two the State taking a more active part in assisting local authorities to recovery While so far as this Bill went he would say for this relief much thanks he contended that it held no solution for the great problem with which they were faced.

Mr KINGSLEY GRIFFITHS said he thought that the formula of the Act of 1929 had stood the test of time and that this revision was another honest effort to meet the addtional necessities that had arisen since that year He therefore gave it a very hearty welcome, within its limited scope

After further debate Sir FRANCIS FREMANTLE said that he thought the passing of the Local Government Act of 1929 had been a tremendous step in advance To test the first seven years experience of the system he took the figures for infant and child mortality which were to be regarded as a good index of public health work. In 1922 deaths among infants per 1000 births numbered 77; in 1929 they had come down only to 74; but in the last seven years they had been reduced to 57, and there was a similar record of progress all along the line For this improvement he held responsible the removing of the percentage grants and the provision of block grants together with the other parts of the 1929 Act. He congratulated the Minister on having brought in a very difficult and unpopular Bill, but one that was nevertheless of great value in promoting public well being.

Mr R. S HUDSON Parliamentary Secretary to the Ministry of Health, replying to the debate, said that one of the main reasons why the Government had abandoned the percentage grant system was that it gave far more to the rich areas that could afford to spend money than to the poorer areas which could not afford to spend money It was because the Government recognised that the poorer towns with low rateable value needed more services and were less able to pay for them by themselves, that they devised this formula which provided weighting for the poorer towns with lower rateable value and higher unemployment. The figures given by the Minister of Health recently in the House about the maternity services completely disproved the statement which was made when the Act of 1929 was going through the House, that the social services would tend to be starved because the local authorities would not have any money to pay for progressive increases Figures from South Wales for example, had shown a substantial increase in the expenditure on maternity services and there was no evidence of starvation there If certain local authorities had not provided enough meals to an adequate number of school children the answer to that was that they could have done so if they had wanted to Whatever might have been the position in the past they would certainly have no excuse for not doing it now under the new increased grants that would be given

The Bill was read a second time and the financial resolution in connexion with it was agreed to in Committee

NOTES ON CURRENT TOPICS

National Health Insurance Bill

In the House of Lords on Feb 25th Viscount GAGE moved the second reading of the National Health Insurance (Amendment) Bill It was he said a purely formal measure which involved no new question of principle or policy It was really a drafting amendment to the National Insurance Act 1936 and it had become necessary through changes of nomenclature introduced by the Pharmacy and Poisons Act 1933 Contracts were made usually by the insurance committee of each county or county borough with chemists for the supply of medicines to insured persons Since the beginning of the national health insurance scheme corporate bodies equally with individuals had been entitled to enter into these contracts provided that dispensing was carried out by or under the direct supervision of qualified pharmacists When the consolidating National Health Insurance Act, 1936, was being framed the persons entitled to undertake dispensing for health insurance purposes were described in language which was considered to be the true effect of existing enactments, but since then doubts had arisen whether the words actually covered the case of corporate bodies, and it appeared that Parliament might unwittingly have deprived them of the rights which they had always had. This Bill substituted more appropriate words with the object of regularising the contracts which had already been entered into with corporate bodies, and of making it clear that they could be entered into in future on the same basis as before the Act of 1936 was passed

The Bill was read a second time and later passed through committee without amendment

Factories Bill

On Feb 25th the Factories Bill was considered by a standing committee of the House of Commons On Clause 1 (which provides that every factory shall be kept in a clean state and the floor of every workroom shall be cleaned at least once a week by washing, sweeping, or other method), Mr R J Davies moved an amendment that such cleaning of floors should be done at a time when work was not going on in the workroom —Mr G Lloyd, Under-Secretary, Home Office, pointed out that the adoption of this amendment would make impossible the position of factories working a three-shift system, and it was withdrawn

CUBIC SPACE

On Clause 2 (which provides that a factory shall be regarded as overcrowded if the workpeople have less than 400 cubic feet of space each), Mr R J Davies moved an amendment to leave out a proviso that for five years the figure should be 250 cubic feet, and should afterwards continue at the lower figure where a workroom had effective mechanical ventilation He said that the whole purpose of the clause was weakened by the proviso —Mr Lloyd said that there was no other way than by these elastic powers to meet the varying conditions of British industry There were small concerns, in which to raise the minimum cubic space per head from 250 to 400 feet—an increase of 60 per cent —would involve hardship, not only on the occupiers but on the workpeople They would not be able to carry on with their existing workpeople and would have either to close down or discharge the extra people who could not be accommodated under the new provisions Modern research had shown that the movement and circulation of air were more important than the actual gross cubic feet of space available On the other hand, the Government recognised that it was desirable in certain circumstances to lay down conditions as quickly as possible They had put down amendments in terms practically the same as those proposed by Mr Davies, and they proposed to take power in special cases to bring the condition as to mechanical ventilation into operation before the end of the five years —Sir E Graham-Little supported Mr Lloyd in his contention that the movement of air was more important than the amount of cubic space allowed All modern research confirmed that —Mr Banfield said they had had some experience of this kind of proviso with regard to underground bakehouses They were presumed to have been abolished by an Act of Parliament passed nearly 30 years ago, but that Act had a proviso of this kind that provided premises were in continuous occupation and complied with a certain amount of cubic air space they could be used as bakehouses In London to-day there were still scores of underground bakehouses which were totally unsuitable He appealed to the Government to lay down a definite period within which the 400 cubic feet provision should come into operation —Mr Short said that he quite realised the importance of some measure of elasticity in legislation, but the proviso as drafted, and even with the amendments proposed by the Under-Secretary for the Home Office, did not, he thought, provide all the necessary safeguards —Mr Lloyd said that the Home Office had endeavoured to meet a number of these points in a spirit of accommodation He had asked one of the factory inspectors to come to that committee room on the previous day and calculate what would be the effect of this provision He (Mr Lloyd) found that under the 1901 Act 132 people could be employed in the room, but working under the present Factories Bill under the 400 cubic feet standard, only 50 people would be allowed He was disposed to believe that on the whole the provisions in the Bill were reasonable The International Labour Office standard was 350 cubic feet, which was less than that in the Bill The Home Secretary would have power to increase the number of cubic feet which must be allowed for every person in special circumstances —Mr Davies, in asking leave to withdraw the amendment, said that they would be compelled to consider the whole of this problem on the report stage. From 1875 a minimum of 300 cubic feet had been provided per person in a common lodging-house, it was wrong for workers in factories to have a smaller space to work in than a tramp sleeping in a common lodging house He looked upon mechanical ventilation in a factory as he did upon artificial teeth in a man's mouth, it was a second best —The amendment was withdrawn

In the House of Commons on March 1st Mr Elliot Secretary of State for Scotland, introduced the Local Government (Financial Provisions) (Scotland) Bill, a measure to amend Part III of the Local Government (Scotland) Act, 1929, and to repeal so far as relating to Scotland Section 45 of the Unemployment Assistance Act, 1934 —The Bill was read a first time.

QUESTION TIME

WEDNESDAY, FEB 24TH

Capitation Fee for Adolescents

Mr Rostron Duckworth asked the Minister of Health whether any agreement had now been reached in respect of the medical fee for juvenile patients shortly to be brought into health insurance —Mr Hudson, Parliamentary Secretary to the Ministry of Health replied No agreement has yet been reached but the matter is again to be brought before my right hon friend by a deputation from representatives of the medical profession very shortly

Industrial Workers and Dermatitis

Mr Gardner asked the Home Secretary whether he would consider giving legal force to an opinion first expressed by his department in 1931 and confirmed by him in a letter, dated Jan 5th 1937, in connexion with an industrial process in which a material known as glass silk was used namely that persons employed in handling this material should be provided with protective clothing, respirators and goggles in order that the admitted risks of dermatitis and irritation of the throat and nasal passages might be as far as possible avoided —Mr Lloyd, Under Secretary, Home Office replied I am advised that the experience of the Factory Department has not proved the effects of this material to be so serious as was feared in 1931, and the Home Office letter of last month did not go so far as to confirm the views expressed six years ago I am however, having special inquiries made with a view to considering what further action is called for

THURSDAY FEB 25TH

The Press and Intrusion into Private Griefs

Sir Assheton Pownall asked the Home Secretary whether he had now heard from the Newspaper Proprietors' Association with regard to the recommendations of its committee on the subject of complaints against certain press representatives —Sir John Simon replied A few hours ago I received a letter from the Newspaper Proprietors' Association which I am causing to be published

[The letter states that the following resolution had been passed unanimously by the Association: The council of the Newspaper Proprietors Association strongly condemn methods of news gathering which may cause unnecessary distress to private persons Cases such as those which have recently received publicity in the House of Commons and elsewhere have the disapproval of all newspapers represented in the council and every effort will be made to ensure that no such charges can be made against them or their representatives. It concludes by saying that the council "will continue to employ every effort to avoid undue and improper intrusion into private griefs. They hope it will be appreciated that freedom in the collection and publication of news is just as important to a free press as freedom in the expression of views, and that all possible facilities will be granted to newspapers to maintain properly and efficiently their service of information "]

Workmen's Compensation

Mr BROOKE asked the Home Secretary if it was the intention of His Majesty's Government to take the necessary steps to bring the law and practice of workmen's compensation in this country into harmony with the principles of the International Labour Convention of 1925, on workmen's compensation, and thus enable this country to ratify the Convention —Sir JOHN SIMON replied: I am advised that this Convention could not be ratified without far reaching changes in the law and medical arrangements of this country and I see no prospect of such legislation being passed at present

Mr BROOKE Can the right hon gentleman say whether the Departmental Committee now considering this matter are also considering whether it is possible to bring the law of this country into harmony with the International Labour Convention ?

Sir J SIMON I know that very far reaching changes are involved

Mr BROOKE Is it not possible to bring the law up to the standard of the International Convention ?

Sir J SIMON: I should like to have notice of that question

Accommodation for Mental Patients in Lancashire

Mr WILLIAM ROBINSON asked the Minister of Health whether in view of the fact that patients at present in various mental hospitals in Lancashire were in excess of the number allowed by statute and that in addition, there were cases awaiting transfer from public hospitals in Liverpool and Lancashire he would make investigations as to the cause of the delay in obtaining the approval of the Board of Control to schemes submitted to them and if he would urge the Board of Control to expedite their approval of the Brockhall certified institution extension scheme which had been under consideration by them for about three years.—Sir KINGSLEY WOOD replied: I am advised that the present inadequacy of accommodation for mental patients in Lancashire is not in any way due to delay on the part of the Board of Control in approving either the Brockhall Institution extension or any other schemes submitted to them by the Lancashire Mental Hospitals Board

Health Insurance Additional Benefits

Mr JAMES GRIFFITHS asked the Minister of Health whether he was aware that the disparity between the additional benefits provided by approved societies under the National Health Insurance Acts was having a serious effect upon the position of the poorer societies; that members were seeking to be transferred to the richer societies that provided the higher additional benefits and whether he proposed to take steps to coördinate the administration of the Acts in such a way as to provide uniform benefits for uniform contributions.—Sir KINGSLEY WOOD replied: I am aware of the considerations mentioned but statutory provision is already made for the protection of any society against transfer of membership due to unfavourable valuation results Equalisation of benefits would be incompatible with the retention of the approved society system of administration and I see no sufficient reason for altering that system at the present time

Lancashire Mental Hospitals Board

Mr KIRBY asked the Minister of Health whether the decision of the Lancashire Mental Hospitals Board to charge the local authorities an additional 2*d* per day per patient had been finally approved; and, if so whether he could give the reason for the proposed increase — Sir KINGSLEY WOOD replied The proposed increase is a matter for the Lancashire Mental Hospitals Board and does not require my approval I understand however that it is due mainly to a rise in the wages bill of the nursing staff owing to the adoption of a shorter working day and to an advance in the price of commodities such as coal and flour

Raw Milk and Scarlet Fever

Mr ROBERT MORRISON asked the Minister of Health whether in view of the evidence contained in the annual report of the chief medical officer of his department for 1935 of serious outbreaks of scarlet fever solely due to the sale of raw milk he would consider the making of regulations providing for the compulsory pasteurisation of all milk.—Sir KINGSLEY WOOD replied: I have no power to make such regulations

Water Pollution near Manchester

Mr McGHEE asked the Minister of Health if his attention had been called to the serious pollution of the water supply at Ringway near Withenshawe Manchester; and what steps he proposed to take to secure adequate supplies of pure water to the residents of this area — Sir KINGSLEY WOOD replied Yes, Sir I am communicating with the Manchester Corporation with a view to arrangements being made to provide a pure supply at an early date

MONDAY MARCH 1ST

Illness among Post Office Employees

Mr VIANT asked the Postmaster-General if he would give the number of employees in the London district of the Post Office engineering department who were absent through illness and the average duration of such illness, for the years 1934 1935 and 1936 and the number of employees employed for each of the aforementioned years —Major TRYON replied as follows

Year	No of employees.	Absent at any time during the year on sick leave	Average sick absence per person employed (in days)
1934	9,300	4028	8 8
1935	10 177	5390	8·2
1936	11 068	6187	7 7

Air Raid Precautions

Mr WILSON asked the Home Secretary what plans had been made by the Air Raid Precautions Department for the provision of gas-proof shelters for public use equipped with filtration units and pumps.—Mr GEOFFREY LLOYD replied: It is proposed that as far as possible members of the public should remain indoors in a part of their home or place of work which has been adapted as a refuge in accordance with instructions which will be issued. The question of the provision of refuges for persons caught in the street when a raid is imminent is under consideration; but while the equipment required in public refuges must depend on the nature of the premises employed for the purpose it is considered that if ordinary safeguards are employed the installation of filtration plant will not be required

Mr WILSON asked the Home Secretary whether the Air raid Precautions Department could state by what test in their opinion, ordinary people could detect the presence of mustard gas or lewisite without having to breathe it —Mr GEOFFREY LLOYD replied Mustard gas and lewisite can be detected by visual observation or by sense of smell, which might suffice to give warning without any harmful effect Arrangements will however be made for the detection of poison gas as part of the air raid precautions organisation and if members of the public were in danger of inhaling poisonous vapours every effort would be made to warn them of the presence of gas before they had to ascertain it for themselves

TUESDAY, MARCH 2ND

Council of College of Nursing and Industrial Nursing

Mr ROSTRON DUCKWORTH asked the Home Secretary whether he had received any memorandum indicating the policy of the council of the College of Nursing with regard to industrial nursing and to the care and health of the employees in factories, and whether, in that case, he would see what practical steps could be taken to give effect to its recommendations —Sir JOHN SIMON replied Since the question was put down I have, as no doubt have other hon Members, received a copy of a memorandum on this subject from the College of Nursing, and it will receive my careful consideration The policy of the College, of which I have been kept fully advised is to provide special training for nurses employed in industrial undertakings or wishing to take up such employment This policy has the full support of the Factory Department and both medical and other inspectors have given lectures to the nurses attending the courses

Protection against Arsenical Gas

Mr PARKER asked the Home Secretary what was the rate of rise of pressure across the filter when arsenic smokes were present in the area in a concentration of 0 6 gramme per cubic metre and were breathed through a civilian *respirator* —Mr GEOFFREY LLOYD, Under Secretary, Home Office, replied The concentration of arsenical gas mentioned in the question is extremely high and such as can only be produced in quite exceptional circumstances It is considered that such concentrations are unlikely to be encountered by the general civilian population under ordinary practical conditions, and the question as to the behaviour of the civilian respirator under these hypothetical conditions has, therefore, no practical significance

MEDICAL NEWS

University of Oxford

On Feb 27th the honorary degree of D Sc was conferred on Prof T Svedberg of Upsala After the congregation Prof Svedberg brought into use the ultra-centrifuge in the department of biochemistry and demonstrated its action. He is its inventor and maker (see *Lancet* 1936 2 874)

The degree of D.M was conferred on W H Owles and D H Brinton

Last Saturday Sir Arthur Salter was returned to Parliament at the Oxford University by-election He stood as an Independent and received 7580 votes, against 3917 given to Sir Farquhar Buzzard F R C P (Conservative) and 3608 to Prof F A. Lindemann, F.R.S (Independent Conservative)

At a congregation on Tuesday Sir Farquhar Buzzard regius professor of medicine in the University moved a decree that a special allowance of £500 a year be paid to any Nuffield professor who undertakes not to retain fees given him for attendance on patients in hospitals associated with the Nuffield scheme A professor could thus give up his fees for an annual payment and his services would be at the disposal of patients and colleagues in cases of special interest

University of Cambridge

Mr James Gray Sc.D reader in experimental zoology in the University has been appointed to the chair of zoology in succession to Prof J Stanley Gardiner F R.S who is retiring at the end of September

Royal College of Surgeons of England

The spring course of museum demonstrations at the Royal College of Surgeons has begun and to-day Friday Dr A J E Cave will give the second when he will speak on anatomy of the knee joint He will also demonstrate the anatomy of the nasal fossæ and sinuses on March 12th and of the trigeminal nerve on March 19th The remaining lectures will be given on March 8th by Dr L W Proger who will describe recent additions to the museum and on March 15th by Dr C Keith Simpson, who will speak on the pathology of the adrenal gland in relation to sudden death All the demonstrations will be given at the College Lincoln's Inn fields, W C at 3 P M and they are open to advanced students and medical practitioners

Increased Use of Milk

Sir Kingsley Wood with Lord Feversham (Parliamentary Secretary to the Ministry of Agriculture) received on Tuesday last a deputation from the National Federation of Women's Institutes, introduced by Lady Denman The object of the deputation was to bring to the notice of the Minister of Health a resolution urging the Government to take such action to reduce the retail price of milk as would operate without detriment to the producer They said their inquiries showed that owing to the high price of milk its consumption in rural districts, which was already low was decreasing and the taste for milk lessened They thought it impossible for a family to purchase the amount considered necessary for good health on the wage of an agricultural labourer Sir Kingsley Wood in reply said it was beyond question that we should as a country drink much more milk. Moreover it was important to emphasise that the milk we consumed should be safe clean and wholesome After speaking of the steps already taken to increase consumption of milk (the milk in-schools scheme ; distribution of liquid or dried milk by over 400 maternity and child welfare authorities ; the work of the National Milk Publicity Council and experiments by which the Milk Marketing Board provided milk at reduced rates in the Rhondda at Jarrow and elsewhere) he said that the far reaching recommendations made in the recent report of the Milk Reorganisation Commission were now being considered by the Government In many areas including the necessitous areas, local authorities would if Parliament approved the proposals now before it have increased resources after April next to provide milk, free of charge or at a reduced rate for mothers and young children as well as school-children

Marie Curie Hospital

Queen Mary has consented to visit this hospital on Friday March 19th to open the Helen Chambers research laboratories.

British Red Cross Society

The Queen has assumed the office of president of this society and the Duke of Gloucester has become chairman of the council in place of his brother who is now King and who becomes patron of the society

Eichholz Clinic

Sir Humphry Rolleston has accepted the chairmanship of the medical board of this clinic in succession to the late Lord Moynihan. The clinic employs a staff of blind chartered masseurs and is administered by the National Institute for the Blind

Margaret street Hospital London

At the annual meeting of this Marylebone hospital for diseases of the chest it was stated that the out patients have increased this year to 160 per week as compared with 144 per week last year owing largely to treatment given in the X ray clinic

British Institute of Philosophy

An address will be given by Mr N J T Needham Sc D entitled Should Our Rulers be Biologists on Tuesday March 16th at 8 15 P M at University College Gower-street London W C Prof Lancelot Hogben F R S will take the chair and cards of admission may be obtained from the director of studies at University Hall 14 Gordon-square W C 1

Royal Society of Medicine

This society's house and library will be closed from Friday March 26th to Monday March 29th both days inclusive The library will be closed at 6 30 P.M on Thursday March 25th and on Tuesday March 30th

Institute of Hospital Almoners

Dr A B Howitt M P took the chair at the annual general meeting held at the Westminster Palace Rooms on Feb 25th when Sir George Newman gave an address He had learned Sir George said the philosophy of almonry from Jeremy Bentham Edwin Chadwick Florence Nightingale Thomas Barnardo and Robert Morant Originally the hospital almoner's work was to assess collect and adjust the voluntary payments of patients, but it had now become a great educational and creative movement for it was coming to be realised that medicine must be social as well as medical and that disease was the biggest factor in industrial welfare It was clear from what was said at the meeting that the demand for almoners still exceeds the supply and there is a temptation to shorten the period of training in order to meet it but the council of the Institute is setting its face against any lowering of the standard or shortening of the period of training

Hospital Saving Association

The sum of £502,492 was paid to London hospitals last year (ending June 30th) by the association and some £58,051 to provincial hospitals These sums together with refunds amounted to £704,451

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Swinton (Lancashire) Sudbury (Suffolk) Chertsey (Surrey) and Staveley (Derbyshire)

Medical Referee under the Workmen's Compensation Act 1925 for the Oban Sheriff Court District (Sheriffdom of Argyll) Applications should be addressed to the Private Secretary Scottish Office Whitehall London S W 1, before March 24th

NOTES, COMMENTS, AND ABSTRACTS

THE SAILOR LOOKS AT THE SURGEON

In an address delivered at the Royal Naval Hospital Chatham, last November and published in the January issue of the *Journal of the Royal Naval Medical Service* Admiral Sir Edward Evans expressed admiration of the surgeons whom he has known and of the profession as a whole He referred to Edward Wilson whose name is a revered memory and whose knowledge of food values enabled us to get the best possible sledging rations for that long eighteen hundred mile sledge journey to the South Pole and back. Wilson was known to the expedition as Uncle Bill or The Peacemaker and Admiral Evans ended his tribute by quoting Scott's very moving letter to Mrs Wilson in which Scott says of Wilson he died as he lived a brave true man—the best of comrades and the staunchest of friends—an enviable epitaph indeed In the second part of his address Admiral Evans dealt with the medical aspect of polar exploration from the point of view of a sailor-explorer Exploring is an occupation for youngish men from 27 to 35 seems to be the best all round age though the leader may be older Men over 25 seem to stand the long sledge journeys better than their juniors In selecting personnel the medical officer may be invaluable Temperament as well as physique must be considered and Wilson with the help of Murray Levick and Atkinson examined nearly 8000 volunteers for the Scott expedition Provisions on board the ship or at the main base can obviously be more lavish than sledging rations which on the Scott expedition consisted of 34 4 oz. daily for each man made up of 16 oz of biscuit 12 oz. of pemmican 2 oz. each of butter sugar and eating chocolate and 0·4 oz. of tea and cocoa Sometimes this ration was supplemented by fresh pony meat but a surfeit of this was apt to cause dysentery Lice are mercifully unknown in the Antarctic—a matter for thankfulness when clothes can only be washed at the winter quarters and when it may be necessary to go as long as 150 days without washing shaving cutting the hair or cleaning the teeth Apart from frost bite and snow blindness chafe a seemingly minor disability may become a major handicap Admiral Evans himself fell a victim to scurvy which started with stiffening of the knee-joints so that he was unable to straighten his legs. Nevertheless he managed to stagger along for over 100 miles in this sorry plight till he finally fainted and dropped in his tracks on the ice. Thanks to the devotion of his companions he was rescued and treated so successfully that less than a year later he was fit enough to take command of the expedition on Scott's death. In comparing the great explorers he has known who continued to strive to seek to find and not to yield with the medical profession *Admiral Evans paid it the highest compliment*

MEDICAL TREATMENT OF HEPATITIS AND CHOLECYSTITIS

Dr Adam Moss (West Kirby) writes: In the report of the discussion at the Liverpool Medical Institution given in The Lancet of Feb 20th I find no mention of the treatment of hepatitis and cholecystitis with vaccines Twenty years ago I saw a young lady who suffered from frequent attacks of jaundice and fever She had been seen by physicians in Manchester and Liverpool the burden of whose treatment was hexamine; which was given without effect. It struck me that the condition might be due to *an infection of the gall bladder and that a* vaccine might prove useful As I did not know what the particular organism was I injected ten minims of Parke Davis's Mixed Infection Phylacogen weekly for about 18 doses The result was a complete cure and since then I have treated all these cases in the same way and with almost complete success. A few years ago Sir David Wilkie published a paper in which he said that for the five preceding years he had sent all excised gall bladders to the laboratory for culture No organisms were found inside the gall bladder but in 75 per cent. the hæmolytic streptococcus was found in the wall He concluded by saying: "I do not know of any drug which is likely to reach this, perhaps a vaccine would. I then found that the toxin of the hæmolytic streptococcus was one of the nine contained in the phylacogen.

FREE CONVALESCENT HOMES

Doctors who have worked through the recent influenza epidemic will undoubtedly have met with patients who would be greatly benefited by a period of convalescence away from their own homes but who are prevented from going away by lack of means It cannot be widely enough known that the Metropolitan Convalescent Institution exists to meet the needs of such patients The Institution has homes for both sexes at Walton near Weybridge, and Bexhill-on-Sea, and a home for children at Broadstairs Much has recently been done to bring the buildings up to date and more is contemplated as soon as funds permit It should be emphasised that no charge whatsoever is made to the patients who are admitted by subscribers letters and who receive concessions in the matter of railway fares. Further information may be had from the *secretary* at 14 Victoria-street London S W 1

COLOUR BLINDNESS AND HÆMOPHILIA

Since colour-blindness and hæmophilia are sex linked characters, the genes responsible for these defects should be carried in the same chromosomes and should show also partial linkage with one another Such a relation was demonstrated by Dr Julia Bell and Prof J B S Haldane F R S before the Royal Society on Feb 25th in three of six families having both conditions. In these three all the hæmophilics were also colour-blind while without exception their non hæmophilic brothers had normal vision Though in another family the linkage was doubtful for two brothers were colour-blind but only one had hæmophilia in the two remaining families it was the non hæmophilics that were colour blind This was attributed to crossing-over of the genes It was calculated from the frequency of crossing-over and of colour-blindness in the male population that the probability was very remote that sampling had caused the association attributed to linkage Dr Bell and Prof Haldane also obtained further evidence for the view that hæmophilia originates by mutation

ADVICE ON CHILDREN

The number of books now being issued by doctors on the upbringing of children seems to be interminable A recent addition [1] is one of a series in which Commonsense figures prominently in every title It is perhaps unfortunate that Dr Scott had confused common sense with chattiness In a prefatory bed time story all children are told to chew each bite thirty two times or more which alone should be enough to frighten off the average parent who already finds children's meal times tedious enough A chapter devoted to the dangers of poisoning by deadly night shade berries on the other hand will hardly frighten doctors for few of them have heard of a case of this form of poisoning except from their old nannies In brief the book is not (as Dr Scott would say) our cup of tea A smaller book,[2] which has an attractive frontispiece is sponsored by the Associa tion of Maternity and Child Welfare Centres Dr Gibbens is clearly attempting to deal with those problems on which the inexperienced parent needs advice, and if his views on such matters as child psychology are a trifle over-simplified and didactic, no great harm is done We hope those wicked women who provide candied fruits and all manner of indigestible foods at children's parties, at whom Dr Gibbens shakes such a terrifying fist, will be suitably humiliated. The book contains a surprising amount of information in small compass and deserves success

A BEDSIDE BOOK

THE bedrooms of many conscientious buyers of "bedside" books must nowadays be so congested as to resemble public libraries, but the tired doctor might do worse than add to his collection a small book [1] in which Dr Christopher Howard has set down his observations on some of the things encountered in the course of his work or read of during his leisure Since his thoughts on any given theme occupy often less than a page of the book, it is not to be expected that they will always be very profound nor that his judgments will be particularly searching Nevertheless, what he has to say is said with freshness and often with humour When, in discussing modern methods of anæsthesia in childbirth, he says that "there are now women who do absolutely nothing for themselves except pass their own water" and that "it is doubtful if they would even do this were not repeated catheterisation a dangerous and a painful proceeding," it is to be hoped that he is talking only of parturient women. Dr Howard's likes and dislikes are positive enough Thus he approves of good food and drink and good cigars, whereas for contraception he has nothing but contempt Dip into it where he will, the medical reader will find something to amuse him in this little book and little or nothing to irritate him

A USEFUL MAGNIFIER

WE have received from Messrs C Baker (244, High Holborn, London, W C 1) a new form of magnifier which should be found useful in laboratory work of many kinds It consists of a four inch convex meniscus mounted on a tripod with legs about 2½ in long, which can be extended or unscrewed for packing flat The lens gives a magnification of about 2½ times and has a flat field remarkably free from distortion The tripod is wide enough to stand over a Petri dish, and there can be few bench occupations for which such a magnifier would not be helpful More than that, it would be useful on the desk of any doctor, whose own crystalline lens is beginning to harden, for reading difficult print or small writing The mount is a brass casting, heavily crystallined, and well adapted to withstand wear and tear The price is 17*s* 6*d*

OBSTETRICAL NARCOSIS WITH EVIPAN

AT a meeting of the Danish Association for Gynæcology and Obstetrics last year, Dr Ekkert Petersen gave an account of his experiences with Evipan in 100 consecutive confinements from the beginning of 1935 to the middle of October of the same year Since then his experience in this field has grown considerably, but his analysis concerns his first 100 cases (*Hospitalstidende,* Dec 8th, 1936, p 19) There were 72 primiparæ and as a rule the duration of the narcosis was from 20–25 minutes The proper timing of an injection was easiest in primiparæ When it had been given too early, and the narcosis began to fail before the birth of the child, the original injection could be supplemented by another, smaller injection without any risk. The action of the evipan was prompt, and in only one case was pain complained of at the time of the child's birth, some 15 minutes after the injection In most cases the narcosis continued for a little while after the child's birth, occasionally till after the delivery of the placenta In the 10 cases in which tears of the perineum occurred—they were all small—the practice was adopted of suturing the wound before the delivery of the placenta in order to exploit what was left of the narcosis Petersen has studied his material with special reference to certain features such as the labour pains and the amount of post-partum hæmorrhage With regard to the former, both labour pains and abdominal pressure were satisfactorily maintained, only the first and occasionally the second labour pain following the injection being weakened As for post-partum hæmorrhage and atony of the uterus, they seem to have been less than what is expected as a sequel to obstetrical chloroform narcosis Only in one case was there retention of the placenta requiring Credé's manœuvre In no case was aceton uria observed None of the infants showed asphyxia or apnœa In the comparison Petersen draws between obstetrical chloroform and evipan narcosis, his verdict is in favour of the latter

NAVAL COOKERY

TIME was when the sea-cook was referred to derisively as "slushy" and to be called the son of a sea-cook signified contempt The "Manual of Naval Cookery" now issued by H M Stationery Office at 3*s* 6*d*, proves that the status of sea-cooks has risen, and no modern sea cook's child need be ashamed of his origin. This manual, 200 pages long, is a mine of information and includes chapters on spices, invalid cookery, breadmaking, on cooking in small quantities, and on cooking for a general mess Whatever ichthyologists may say, it seems that, culinarily speaking, there are only three kinds of fish the oily, the white, and the shell The description of fresh fish almost sings itself "The eyes are full and bright, the gills are a clear bright red" Stale fish, on the other hand, "are soft, the eyes are sunk in the sockets, their flesh pits on the slightest pressure, and is easily torn from the backbone" Clearly, the crier of stinking fish must expect short shrift from the sea-cook familiar with these physical signs Eight pages are devoted to sauces, ten variations on the theme of White Standard Sauce are described and four on the Brown Standard, one of which, Devil Sauce, made by adding French mustard, Worcester sauce, and Cayenne pepper, should tickle the most jaded palate So excellent a book might find an honoured place in other places besides the galleys of H M ships

---

TREATMENT OF STREPTOCOCCAL INFECTIONS —Referring to an annotation on p 525 of last week's issue of THE LANCET, Messrs Pharmaceutical Specialities (May and Baker) Ltd point out that their antistreptococcal remedy Proseptasine differs from the preparations of *p* aminobenzenesulphonamide which we mentioned, since it is the benzyl derivative (*p*-benzylaminobenzenesulphonamide) and in their experience is less toxic

DISFIGUREMENT BY VACCINATION —Major R F C AUSTIN, R A M C, retd, writes "I have been asked by a young Oxford undergraduate to remove what he considers the disfiguring marks of three vaccinations performed in his childhood Could any fellow practitioner tell me of a safe method of doing this?"

HORNSEY WELFARE CENTRE —Sir Arthur MacNalty, the chief medical officer of the Ministry of Health, opened a new maternity and child welfare centre at Hornsey on March 1st The reduction of infant mortality he said gave ground for hope that a corresponding advance might be made in protecting children in the next important stage of life—the "toddler" stage He emphasised the value of continuity of medical supervision before and after school age was reached, and the need for coöperation between the maternity and child welfare service and the school medical service

ADDRESSES AND ORIGINAL ARTICLES

THE TREATMENT OF ACUTE RHEUMATISM IN CHILDHOOD *

BY REGINALD LIGHTWOOD M.D F.R.C.P Lond.

ASSISTANT PHYSICIAN FOR DISEASES OF CHILDREN AT THE WESTMINSTER HOSPITAL; AND PHYSICIAN TO OUT PATIENTS AT THE HOSPITAL FOR SICK CHILDREN GREAT ORMOND-STREET LONDON

EXCEPT for the passing fads and phases familiar in all diseases whose treatment is difficult, the therapeutics of acute rheumatism cannot be said to have undergone, for many years any fundamental changes True it is that there is less enthusiasm for the salicylate compounds than was the case at the beginning of the century yet these drugs are still employed and it is also a fact that nowadays we insist upon long periods of complete rest in rheumatic fever chorea, and carditis yet the importance of rest has been known for many decades Perhaps the main changes in our attitude lie in an altered emphasis placed upon the various therapeutic measures a growing awareness of public health to the importance of juvenile rheumatism as a national problem and the organisation of large-scale treatment at considerable outlay by public bodies Apart from further developments along these lines can we expect any great changes or big advances while knowledge of the ætiology of acute rheumatism remains in a state of flux?

Ætiology

Thirty years ago the streptococcal causation of rheumatism was advanced, and in the succeeding years the principal claims put forward by Poynton and Paine have been gradually consolidated not without modification but even to day not all would care to say that streptococcal infection is the basic cause of rheumatic fever Fewer observers are convinced that any particular type of streptococcus is to blame and fewer still can attempt to explain the mechanism by which a streptococcal infection may be followed in one person by recovery in another by rheumatism in a third by chorea, and in a fourth by the apparently unrelated condition of hæmorrhagic nephritis

Of recent years there has been an increasing agreement that there are three phases in an attack of acute rheumatism. The first consists in the manifestations of a more or less acute throat infection the second phase is a latent period of apparent recovery while the third comprises one or more of the following arthritis chorea carditis nodules and rheumatic erythema The symptom free interval of the second phase was recognised by Haig Brown (1886) half a century ago but his important observation remained in temporary eclipse until Schlesinger (1930) and other workers began to draw attention to it As Schlesinger Sheldon (1931) and Coburn (1936) have been pointing out an understanding of the changes taking place during the silent interval would certainly teach us much of the mechanism which determines the occurrence and severity of the rheumatic attack. In this direction the work of Coburn is particularly stimulating for he has begun to analyse the way in which the immunological changes which follow a streptococcal infection vary in different individuals and to ascertain what special differences are to be noted in rheumatic subjects From his work it emerges that rheumatic children handle a streptococcal throat infection in a manner different from other persons and there is hope that the time may come when we may be enabled to make a rational attempt to correct the abnormal reaction of the rheumatic subject to the streptococcal infection

Without doubt the streptococcal hypothesis is the favourite, but once again a rival has entered the field. Amies and Signy have looked for and found elementary bodies in pericardial exudates obtained from patients suffering with acute rheumatism they have attempted in collaboration with Schlesinger (1935) to show their specificity by agglutination reactions in the serum of rheumatic subjects. If and when this work is confirmed the hypothesis of acute rheumatism as a virus disease (Schlesinger Signy and Payne 1935) will require careful and critical investigation.

Treatment

PREVENTION

Under these circumstances we cannot expect radical changes in treatment until a further lead is given by bacteriology Yet there are certain relatively new observations to encourage us that further progress can be made by the clinician and by the public authorities without waiting for bacterial confirmation of the ætiological hypotheses Now that it has been shown beyond reasonable doubt that the usual sequence of events consists of the three phases —namely throat infection latent period and rheumatic attack—we are in a better position to be on the look out for danger signals and to anticipate the onset of rheumatic disease. It is up to the clinician to make practical use of this knowledge. It is probably correct to infer that without tonsillitis or pharyngitis there would be little if any rheumatism. Thus our first problem is to prevent throat infections in rheumatic children and to this end we ought, I believe to increase our vigilance in the early recognition of tonsillitis in children's hospitals and in convalescent homes where rheumatic patients are undergoing treatment. Curiously enough the most severe attacks of rheumatism are generally preceded by relatively mild tonsillitis so that the transient character of the sore-throat and the small rise in temperature not infrequently cause it to be overlooked and to pass untreated. Sufficient isolation rooms ought to be provided so that every case of tonsillitis among rheumatic children can be separated and, in rheumatic units the beds ought to be well spaced, rather on the lines adopted in isolation hospitals Without these measures we cannot expect to prevent the occurrence of epidemic sore-throat.

[illegible]

The next point concerns the treatment of tonsillitis and pharyngitis [illegible] recurrent infection during convalescence from rheumatism Though I have no experimental or [illegible] evidence for it I believe that the moment when we can do most for the rheumatic child is the time when he is undergoing his acute throat infection. It is I find, particularly [illegible] need in hospital practice that thorough treatment [illegible] the acute tonsillitis is not always carried out [illegible] adequate purpose gargles are probably valueless, and [illegible] the [illegible] or painting the tonsils with [illegible] of protargol [illegible] in giving potassium chlorate [illegible] mouth; rest in bed is essential and [illegible]

---

* Contribution to a discussion at the Harveian Society on Dec 11th 1936

not be resumed until the pulse rate and sedimentation-rate are once again normal.

A series of battles have been waged, without very conclusive results, concerning the question of tonsillectomy Statistics have been used to lend force to the arguments on each side To the unbiased onlooker it would seem fairly certain from the figures that tonsillectomy does not protect against rheumatism, nor indeed would a reasonable clinician expect it to do so, for pharyngitis can lead to rheumatism almost as easily as tonsillitis Nevertheless, clinical experience suggests to me that a complete tonsillectomy lessens the number of throat infections and may, therefore, be expected to be a help in suitably picked cases Certainly we ought not to advise the removal of normal tonsils from any child, even a rheumatic one The position now adopted by the experienced clinician can be summed up as follows in a rheumatic child the question of tonsillectomy should depend upon the ordinary criteria which we apply to any other child, if the tonsils are irrevocably infected they should come out, the tonsillar glands and a history of sore throats are our best guides

Modern Methods

REGIMEN

Let us now ask ourselves what are the main points in modern treatment of acute rheumatism and rheumatic carditis, and how do recent observations help us? In hospital units organised for the work of treating rheumatic children, arrangements are made that every patient showing any evidence of rheumatic "activity" is nursed almost flat with but one pillow, is allowed no active movement except of the hands, and is fed by a nurse so that the work of the heart is reduced to a minimum Together with this régime of complete rest some clinicians choose to employ drugs, but of those at present available none is of primary importance When all signs of rheumatic "activity" have passed, a gradual return to ordinary life is permitted For convenience and to guide the nursing staff, a routine schedule may be drawn up

GRADE 1 —Patient nursed lying down, one pillow, fed by nurse

GRADE 2 —Two pillows, semi recumbent, allowed to feed himself

GRADE 3 —Sitting in bed

GRADE 4 —Dressed and allowed on a couch, later walking a few steps

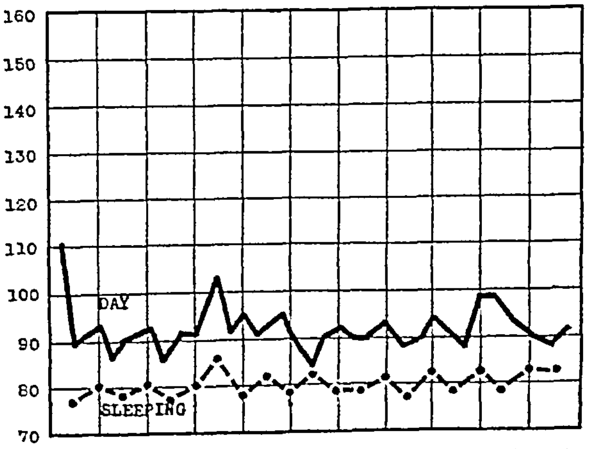

FIG 1.—The normal relation of sleeping and day pulse rates in a child

GRADE 5 —Up half the day

GRADE 6 —Up all day

A similar régime can be employed in a private house provided suitable nursing is available

The definition of rheumatic "activity" is not an easy one, and in some patients it is more difficult than in others Too many doctors make the mistake of relying on the temperature, whereas in fact, the clinical thermometer is not a great help when once the beginning of the acute attack is past, and fever cannot be described as at all constant during the course of rheumatic carditis On the other hand, of real value are careful charting of the pulse rate and weekly estimation of the sedimentation rate (Landau 1933, Payne and Schlesinger 1935) Until the sleeping pulse rate is slow, and the normal relation between it and the day pulse rate is resumed, and until the sedimentation rate is normal on more than one occasion, we ought not to allow the rheumatic subject to be promoted from Grade 1 to Grade 2 (Figs 1, 2, and 3) In patients with uncomplicated rheumatism this promotion can often be allowed after two or three weeks in the slighter cases, and after three to five weeks in ones of moderate severity But when we are dealing with carditis, two or three months is commonly necessary and sometimes many months of complete rest are required When once the stage of "activity" is passed and our patient has been promoted to Grade 2, subsequent promotions are allowed at fairly short intervals, but each patient must be treated individually

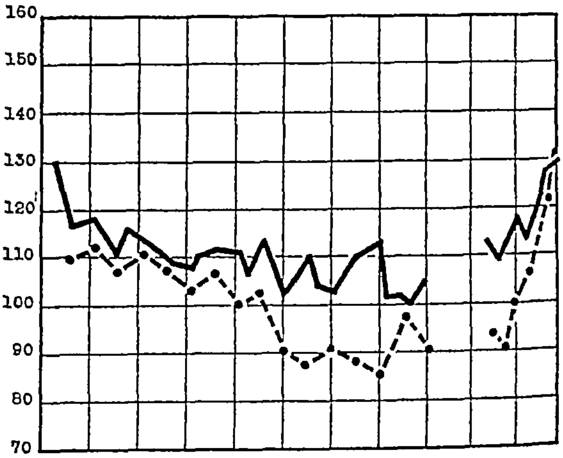

FIG 2 —Sleeping and day pulse rates in a case of rheumatic carditis showing clinical improvement and then after an interval a relapse (on extreme right)

If an intercurrent attack of tonsillitis or pharyngitis supervenes, an exacerbation of rheumatism or of carditis must be feared and a return to Grade 1 is indicated. The use of aspirin to be given during the "silent" period has been suggested as a prophylactic measure, this suggestion being based on the analogy of its effects when used in large doses in animals subject to risks of anaphylaxis It has not yet been proved clinically to be of definite prophylactic value in the silent period.

DRUGS

Many drugs have been used with the object of checking the rheumatic infection and limiting its damage None has emerged triumphant The latest addition to our therapeutic armamentarium is calcium aspirin It is difficult as yet to be convinced that the length of treatment can be reduced by

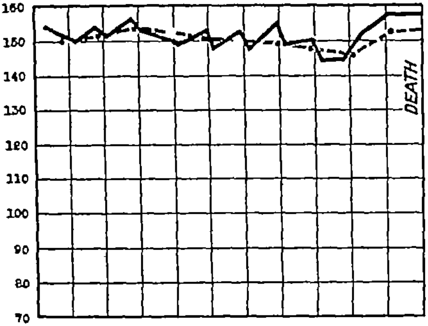

FIG 3—A fatal case of severe pancarditis, showing no interval between the rapid pulse-rates.

using this or any drug The salicylate compounds and aspirin itself are chiefly of value in alleviating the pain experienced at the onset of acute rheumatism.

Conclusion

When the present position has been explored it has to be admitted that we have a very long way to go before we can afford to be complacent in regard to our great problem of treating rheumatism in children. The picture presented by a child who has a slowly progressive rheumatic carditis is one of the most discouraging that the physician has to face If we are honest we must admit to ourselves that, like a fireman with too short a hose we cannot extinguish a smouldering fire licking the edge of the valuables in a locked house whose exterior shows curiously little signs of the damage and danger within for we can do little more than hope that the fire will burn itself out

NITROUS OXIDE ANALGESIA IN OBSTETRICS

A NEW TYPE OF MACHINE FOR SELF ADMINISTRATION OF GAS

By Chassar Moir M D F R C S Edin. F C O G
READER IN OBSTETRICS UNIVERSITY OF LONDON AT THE BRITISH POSTGRADUATE MEDICAL SCHOOL

During recent years much attention has been given to the use of nitrous oxide gas as a means of lessening the severity of the pains of labour With the introduction of automatic apparatus a patient is now able to administer to herself a mixture of gas and air and thus produce a temporary analgesia with each recurrence of a uterine contraction There are two outstanding advantages in this method of treatment: nitrous oxide correctly diluted with air or oxygen is without danger to mother or fœtus and its use does not lessen the frequency or strength of the uterine contractions. On the other hand this type of analgesia falls short of the ideal for the reason that the relief of pain conferred by the intermittent inhalations is often imperfect, and not infrequently so inadequate that the patient has no wish to continue with the treatment

It is the object of this paper to discuss the reasons for unsatisfactory analgesia and to suggest methods by which the results may be improved.

INDIVIDUAL VARIATIONS IN RESPONSE TO NITROUS OXIDE

Before dealing with methods of inducing analgesia with nitrous oxide it may be well to point out that individual patients vary greatly in their response to small doses of the gas This variation is very evident when the gas is used to produce anæsthesia for dental extractions It is not uncommon to find that one patient after inhalation of a small quantity of nitrous oxide will show a deep and comparatively long sustained anæsthesia while another patient after inhalation of a far greater quantity of gas will still be imperfectly anæsthetised and will recover consciousness in a very short space of time

Similar variations of response to nitrous oxide are only to be expected when intermittent inhalations of the gas are given during labour and unfortunately a small proportion of women are so resistant to its influence that it is well nigh impossible for them to obtain a satisfactory analgesia by its use This fact restricts the usefulness of all nitrous oxide machines of the automatic type In order to be safe such machines must necessarily limit the quantity of gas supplied to the patient and not infrequently the restricted amount of nitrous oxide is insufficient to produce an appreciable relief of pain. Should a patient be found to belong to this refractory class it is both useless and unkind to continue with this form of analgesia: a more concentrated nitrous oxide oxygen mixture should be given by an anæsthetist, or alternatively other analgesic agents should be employed.

MACHINES INTENDED FOR SELF ADMINISTRATION OF GAS

The credit for developing a practical form of automatic nitrous oxide machine for the self induction of analgesia goes to Minnitt (1934) who introduced the apparatus now known by his name This machine is adjusted to deliver a fixed concentration of nitrous oxide gas By experiment it was found that 35 per cent. of gas diluted with air is usually capable of inducing analgesia while at the same time avoiding a dangerous cyanosis This machine and others of similar type are now widely used in midwifery practice in this country and have been favourably reported on by various workers and notably by the committee appointed by the British College of Obstetricians and Gynæcologists to investigate the use of analgesic agents in midwifery

This type of apparatus does not however, give uniformly successful results and many obstetricians have been disappointed by the meagre benefits which it confers It has been my experience that while a few patients experience an analgesic effect and are grateful for the relief obtained many others find that the severity of the pains is unaltered. Similar results have been obtained with different machines thus excluding the possibility that the lack of effect was due to defective apparatus

A COMMON CAUSE OF INEFFICIENT ANALGESIA

Observation of patients in labour has convinced me that a common cause of inefficient analgesia is the inability of many women to inhale an adequate amount of nitrous oxide before the full force of a uterine contraction is upon them To keep a mask firmly applied to the face during rest intervals requires a determination which few patients possess, and there are other reasons—of which expense is one—which make it undesirable for the patient to be kept continuously under the influence of the gas throughout her labour In practice, therefore, inhalation of nitrous oxide is always intermittent, and a patient cannot be expected to use the gas machine until there is a warning sensation of a renewed uterine contraction From that moment only 10 or 15 seconds are available in which the gas may be inhaled before the pain becomes distressingly severe Further inhalations demand great self control, and are indeed almost impossible during the second stage of labour for the reason that the patient now has an irresistible urge to "bear down" For the great majority of patients the degree of analgesia is, therefore, determined by the amount of gas which can be inhaled during the short period of 15 seconds which precedes the climax of each pain.

EXPERIMENTAL OBSERVATIONS

To gain information regarding the effect of such short administrations of nitrous oxide, experiments were performed in order to observe and to record the sensations experienced when the gas is inhaled in the manner adopted by the patient in labour These observations were made by myself and by volunteers

Measurement of the analgesic effect of nitrous oxide presents great difficulties and has not been attempted It is, however, a simple matter to observe the characteristic "dizzy" or "light" sensation which is induced by the gas, and to use this as a measure of the efficiency of the various methods of administration The time of onset and the time of maximum intensity of the induced sensation can both be accurately recorded, and although there is no precise "end point" the duration of effect can also be observed The intensity of effect cannot be measured by any yardstick, but it is quite possible to record in rough fashion one's impression of the relative strength of the sensations produced by various methods of administration

Experiments with 35 per cent gas air mixture were made with the aid of a commercial form of machine designed to deliver this concentration of nitrous oxide, the experiments with pure gas were made with the machine which will be presently described. The results are shown graphically in Fig 1

The most obvious experimental finding concerns the intensity of the sensations induced by different concentrations of nitrous oxide gas Pure gas, inhaled for only 12 seconds (two deep breaths) was found to produce a considerably greater effect than the diluted gas inhaled for 30 seconds More over, if inhalation of the diluted gas was also restricted to 12 or 15 seconds—which represents the usual time available before the climax of a labour pain—its action was greatly reduced, and by comparison with pure gas was almost insignificant in effect

Passing now to the speed of action, it was found that the diluted gas does not begin to take effect until nearly 30 seconds after the start of the inhalations, although forced deep breathing will reduce this time to about 25 seconds On the other hand, pure gas was found to take effect in 16 seconds, thus giving it a type of action well suited for the relief of the rapidly developing pain of a uterine contraction

Further experiments showed that five or six deep and moderately rapid breaths of pure gas do not in a normal person produce cyanosis, while even two such breaths are, as will be shown, sufficient in most patients to produce an appreciable degree of analgesia.

The effect of nitrous oxide reaches a maximum about 20 seconds after removal of the mask This increase of action is important when short administrations of gas are given for analgesic or for anæsthetic purposes

AN IMPROVED INTERMITTENT METHOD OF ADMINISTRATION

Since the pains of labour are intermittent, and since there is but short warning of their approach, it is essential that nitrous oxide gas should be given in a manner that will secure as speedy an analgesia as possible As has just been stated, this speed is best achieved by the use of pure gas

Hitherto, machines designed for self administration of nitrous oxide have depended for their safety on an automatic dilution of the gas with approximately 65 per cent of air If such machines were to be adapted for the delivery of pure gas it was clear that some new means of securing safety would have to be employed It occurred to me that this problem could be easily solved by introducing a device which would prevent the patient from obtaining more than a limited quantity of the gas at one time Thus, it would be a simple matter to provide a bag containing sufficient gas for two deep breaths only After emptying, this reservoir could be very slowly replenished by gas issuing from a fine nozzle When full the bag could be made to press on a cut-out lever, thus checking any further delivery of gas It will be seen that the principle is exactly similar to that of the familiar water cistern a fixed supply of water is held in the tank, the water can be withdrawn rapidly, but is slowly replaced, so that the tank is replenished only after the lapse of a considerable interval of time

The practical difficulties in constructing a machine to work on this principle have been very successfully overcome by Mr Charles King, to whom I am much indebted for help

The machine as now constructed by Messrs A Charles King Co, Ltd, London, W 1, uses as reservoir a rubber bag of [illegible] gallon capacity connected on the one side to the nitrous oxide supply and on the other to a delivery tube and face piece The filled bag automatically cuts

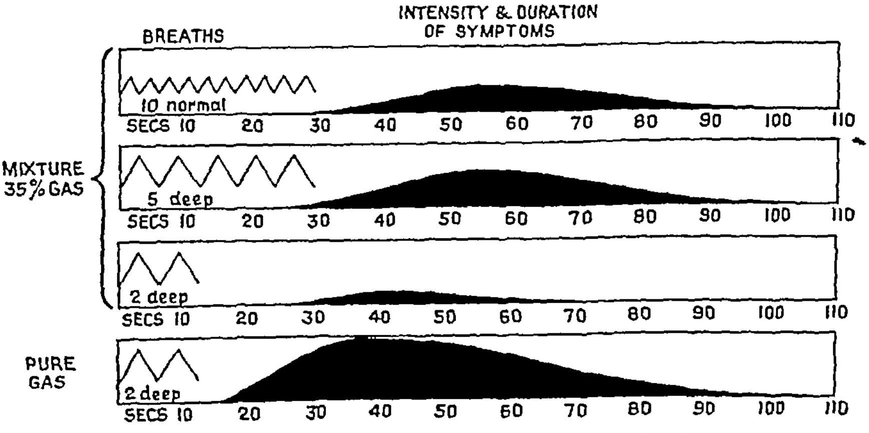

FIG 1 —Comparison of the effects induced by nitrous oxide gas when inhaled in different manners

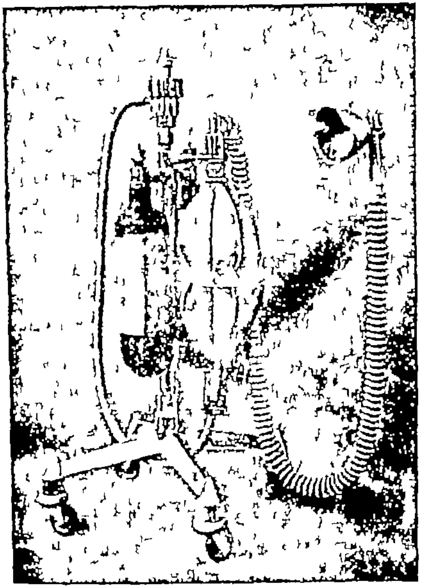

FIG 2.—The new type of nitrous oxide machine.

off the gas supply by the usual method of forcing outwards two levers, which obstruct the inflow tube Escape of gas through the exit tube is prevented by a weighted valve which is however easily lifted by the slight suction of an inspiratory effort This valve also acts as a non return valve so preventing dilution of gas by exhaled air The high pressure gas from the cylinder is reduced by an Adams valve to 5 lb per square inch Between the reducing valve and the bag is placed a fine carburettor jet through which low pressure gas flows at such a rate that a full minute is required for the reservoir to be replenished to capacity The face piece is an improved type which can be repeatedly sterilised by boiling Mounted on it is a small valve which allows the escape of exhaled air (Fig 2)

The machine is simple in construction; there are no adjustments to regulate there is no pressure gauge; nor is there need for an on and off plunger on the face piece—a complication which many patients find difficult to use The machine is comparatively cheap and is economical in use. It has been found that a patient having pains at about 4-minute intervals will consume 50 gallons of gas, costing 3s., in 4 or 5 hours.

This new form of nitrous oxide machine can be used freely whenever labour pains become distressingly severe The patient should be introduced to the machine at an early stage of her labour and given the simple instructions for its use With the first warning of a renewed pain she should instantly press the mask firmly to her face and proceed to empty the bag in two (or not more than three) deep moderately quick breaths The mask is then laid aside in readiness for the next pain The amount of gas used will never make the patient unconscious or prevent her from obeying the instructions of her medical attendant and nurse It will, however confer on the majority of patients a substantial degree of analgesia for about 60 seconds

RESULTS

Great caution must be observed in judging the value of analgesic agents in midwifery A treatment which does not abolish pain but merely lessens its intensity does not lend itself to measurement in terms of efficiency, and the difficulty is increased by the fact that a patient's description of pain is often an unreliable indication of its severity Much also depends on how questions are put and it is not uncommon for different observers to form contrary opinions regarding the usefulness of an analgesic agent in the same patient. Further I believe that statistics based on statements made by patients on the day after delivery are almost worthless. At that time the patient is often in an elated state of mind. Her baby is born and her anxiety is over in these circumstances she has a softened recollection of her troubles of the previous day and tends to praise any treatment which may have been given. If she has had chloroform for the final stage of labour the blunting and confusion of the memory may be very conspicuous and there is often a curious amnesia for the events preceding the administration of the anæsthetic For these various reasons I hold most strongly that the efficiency of an analgesic agent used during labour must be judged *while the patient is still in labour* This important condition has not always been observed in reports dealing with the use of analgesic drugs in midwifery

When judged by the foregoing standards the new form of nitrous oxide machine has given results which are surprisingly good. For each case a record was kept of the observed effect of the gas and of the parturient patient's opinion of the value of the treatment. Of 100 patients, 70 stated that they got good or very good relief of pain from inhalation of the gas, while a further 14 women described the effect as being fairly good In some cases the benefit obtained was remarkable. Thus it has happened on several occasions that a patient has declared that the gas prevented a pain from developing—meaning by this that she believed that the course of labour was being delayed Yet observation has shown that the uterine contractions were in no way impaired although the associated pain was abolished

On the other hand, 16 patients stated that the gas gave no help or that it only 'helped a little For reasons previously stated, a certain number of refractory patients must be expected. This group includes patients who for one reason or another could not follow the simple instructions for using the apparatus Some women have too little intelligence or self control to inhale in the required manner and others cannot be made to understand that the mask must be firmly pressed to the face It is seldom that an intelligent and coöperative patient fails to get substantial relief from use of the new machine

Apart from patients statements, it is my own opinion and the opinion of labour ward nurses, that patients are, almost without exception, considerably quieter and less exhausted by labour pains while making use of the new form of gas machine

Every patient likely to give a considered opinion was asked to compare a machine of the type delivering a gas air mixture with the new form of machine With two possible exceptions every woman who obtained relief from the use of gas expressed a distinct preference for the new type of apparatus One of the exceptions was a woman who declared that she got equally good relief from either machine The other was a patient who said that she preferred to use the gas air machine I did not myself see this patient during labour, but a later conversation with her left me with the impression that her testimony was of doubtful value

In the series of patients just described, gas analgesia was used throughout the greater part of labour Before the "pains" became fully established it was customary, however, to give one or two doses of tincture of opium together with chloral hydrate and potassium bromide During the final stage of labour, when the vulva begins to distend, most women become too restless to attend to a face mask and to force themselves to breathe in the correct manner Generally speaking, therefore, the use of gas should not then be persisted in, and in the present series chloroform was usually administered, preferably by the Young Simpson inhaler In several instances, however, a patient obtained so much relief from the gas machine that she refused to give it up, and was successfully delivered while still under the influence of the self administered nitrous oxide

There were no maternal deaths in this series Five patients were delivered with forceps Stillbirths numbered two one of these was a fœtus showing advanced maceration (one of a twin pregnancy) The other was a stillbirth which resulted from a prolonged labour complicated by early rupture of the membranes, in this case, too, the umbilical cord was tightly twisted round the fœtal neck

THE POSSIBILITY OF CYANOSIS

In the 100 cases described, a careful watch was kept for the possible occurrence of cyanosis This condition was never seen in obvious form * In four patients, however, it was thought that an intermittent slight cyanosis appeared, although in at least one of these cases there was difference of opinion regarding its presence In considering this matter it is necessary to bear in mind that many patients show considerable congestion of the face during bearing down efforts, and it is therefore not easy to decide whether a slight and transient duskiness is to be accepted as a token of anoxæmia due to the inhalation of pure nitrous oxide gas In none of the four cases was any harmful effect observed, and I believe that serious anoxæmia need not be feared for the reason that the periods during which oxygen is withheld rarely endure for even 15 seconds It would, however, be ordinary prudence to avoid even this reduction of oxygen intake in a woman suffering from cardiac failure or other form of respiratory distress for such a patient some other form of analgesia is obviously indicated

COMPARISON WITH OTHER FORMS OF ANALGESIA

In conclusion it may be fitting to compare the method of analgesia described in this paper with other methods which are in common use

Scopolamine and morphine, Nembutal, Sodium Amytal, and other barbiturates, either by themselves or in combination with other narcotic drugs, all have the disadvantage of erratic action; and in large dosage they are unsafe Rectal injection of ether and of paraldehyde, while reported to give excellent results by some workers, are methods which have not been generally favoured in this country, partly because of the difficulty of administration, and partly because of the variable effects produced All these drugs have the additional disadvantage that the patient becomes stuporose (in some cases restless) and must be kept under constant observation It is also generally agreed that the course of labour is delayed by their use Nitrous oxide analgesia, on the other hand, has the great advantage that the patient's coöperation is maintained, and that her labour is not hindered.

For the patient who can afford to have an anæsthetist in attendance throughout labour, nitrous oxide and oxygen can be used with almost ideal results Such a patient has the advantage that the concentration of gas can be varied to suit requirements, and even if she belongs to the "refractory type" the treatment can still be used with a fair degree of success For the less fortunately placed patient the new type of automatic apparatus gives results which, although admittedly less perfect are nevertheless surprisingly good This new machine is undoubtedly more effective in relieving the pains of labour than the type which depends on dilution of gas for the ensuring of safety It is simple and reliable, and has proved itself to be a very valuable addition to the equipment of a labour ward

SUMMARY

1 There are important advantages in the use of nitrous oxide gas as a means of securing analgesia during labour

2 Machines designed to deliver diluted nitrous oxide are often inefficient in relieving pain for the reason that it is difficult or impossible for many patients to inhale sufficient gas before the full force of a uterine contraction develops

3 Pure nitrous oxide gas has a much more rapid and intense action than 35 per cent gas air mixture, and is therefore better suited for the needs of a patient in labour

4 A new form of nitrous oxide machine is described which enables a patient to inhale pure gas at regular intervals, and so induce in herself an intermittent state of analgesia Safety is secured by a device which makes it impossible for the patient to obtain more than two deep breaths of gas before the onset of each pain

5 A series of 100 cases is recorded in which the new machine was used with success In the great majority of cases a useful degree of analgesia was obtained

Clinical experience with the new form of nitrous oxide machine has been obtained in Hammersmith Hospital (British Postgraduate Medical School), and I am indebted to the medical superintendent for providing facilities for its use I gratefully acknowledge the help of labour ward sisters in collecting case records The results are published with permission of the medical officer of health of the London County Council

MOTHERS IN SKYE—A new maternity annexe to the John Martin Hospital, Uig, in the Isle of Skye, has recently been opened

---

* In a later series of cases there was one patient who developed obvious cyanosis when she first attempted to inhale gas during a labour pain Later administrations were accompanied by a cyanosis of lesser degree Similar cyanosis followed use of a machine delivering a 35 per cent gas-air mixture This patient had the peculiar habit of almost completely inhibiting her respirations from the first warning of the onset of a labour pain and without gas in any form a distinct duskiness appeared during each pain She was later delivered spontaneously of a healthy baby

TURMERIC (CURCUMIN) IN BILIARY DISEASES

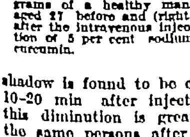
By Albert Oppenheimer, M.D
ASSISTANT PROFESSOR OF ROENTGENOLOGY TO THE AMERICAN UNIVERSITY OF BEIRÛT LEBANON

Turmeric, or *Temoe lavae*, is an oriental plant that for many centuries has been used by the native population of India in the treatment of jaundice The powdered roots and leaves form one of the chief ingredients of curry The botanical name of the plant is Curcuma there are a number of species, among which *Curcuma domestica* and *Curcuma longa* have medicinal value

EFFECTS OF ADMINISTRATION

There are references to the therapeutic use of curcuma as early as 1748 (Loeber) and 1867 (Shortt) The interest of the medical profession and the pharmaceutical industry was reawakened in 1927 when Koch and Guttenberg reported successful treatment of hepatic and biliary diseases with a preparation containing extracts of curcuma. Similar observations have since been published by Kalk and Nissen (1931) Franquelo (1933) Fähndrich (1932) Henning and Künzel (1934) Potter van Loon (1934) von den Velden (1934) Helmy (1935) Vetterlein (1935) and Leclerc (1935) Some investigators used aqueous extracts of the whole root others only the yellow pigment which it contains, called curcumin. Unlike Kalk and Nissen who attributed the therapeutic effect to a number of components extracted from the root, Franquelo and Henning and Künzel were not able to produce in men and animals any demonstrable action except by using an ethereal fractional extract containing curcumin. A solution of pure crystalline curcumin has been proved to cause identical pharmacological effects For practical purposes sodium curcumin is used since it dissolves more readily in water It is with this pigment that I have carried out a series of experiments which begun in 1932, totalled 103 observations in July 1936 The preparations used since 1934 Curcumen or Curcunat contain respectively 0 25 gramme of sodium curcumin in 5 5 c.cm. of water for intravenous injection and 0 1 g sodium curcumin with 0 1 g calcium cholate per dragée for oral administration

In healthy persons intravenous injection of 10 c cm of a 5 per cent sodium curcumin solution produces rapid emptying of the gall bladder clearly demonstrable on cholecystograms The gall bladder shadow is found to be considerably reduced in size 10–20 min after injection. Generally speaking this diminution is greater than that observed in the same persons after a fatty meal containing the yolks of three eggs The tracings here reproduced are taken from the original Röntgen pictures The effect is not constant: out of 31 examinations made for this purpose the size of the gall bladder shadow did not change at all after injection in 6 instances there was only moderate decrease in size in 12 others; the pronounced effect described above was found in 16 persons. I have not been able to ascertain what conditions determine this variability Negative evidence indicates the factors that are *not* involved. The variations are not due to inconstancy of the preparation for the self same solution may empty the gall bladder in one person yet fail to affect its size in another even if used within the same hour; nor are age, sex, body weight, and general habitus involved in this question.



Tracings from cholecystograms of a healthy man, aged 27 before and (right) after the intravenous injection of 5 per cent sodium curcumin.

After oral administration of the dye hardly any changes are apparent in the aspect of normal gall bladders In this connexion it is of interest to note that curcumin is easily absorbed from the digestive tract, and that both in rabbits and in men the pigment is eliminated through the bile-ducts within 15 min. of intravenous injection (Henning and Künzel 1934) During this interval an enormous increase of the outflow of bile subsiding with complete elimination of the dye, has been reported by these authors By means of a special test the dye was eventually found in the urine after both intravenous and oral administration only faint traces were detected in the fæces From these and our own observations one may conclude that curcumin passes through the liver inducing increased secretion of bile and frequently emptying of the gall bladder: in other words its action is both choleretic and cholagogue It is finally eliminated through the kidneys.

Clinically excellent results have been reported in the course of the curcumin treatment of biliary diseases, especially in Germany In these publications however the use of additional measures is invariably mentioned—such as diets of various kinds insulin dextrose, magnesium sulphate, and sundry other variable factors involved in hospital treatment. In an investigation of this kind the therapeutic effect of any form of medication however definite it may seem is difficult to distinguish from that of the general treatment simultaneously adopted, especially in the case of a drug heretofore unknown I have therefore restricted the administration of curcumin to those patients who did not urgently need hospital treatment. Bearing in mind the fact that a large group of biliary diseases would thus escape observation, I have used curcunat since 1933 in the treatment of 67 patients suffering from subacute recurrent or chronic cholecystitis. No other medication was given In all cases animal fat cabbage sardines preserved in oil and mayonnaise dressings were forbidden but no other restriction of diet was imposed and no form of physiotherapy was used. In addition to thorough physical examination and the usual laboratory tests, Röntgen examinations were made regularly except in the presence of severe jaundice. After a number of trials intravenous administration was abandoned for it does not give better results than the more convenient oral method. The intravenous injection of curcumin should be reserved for those conditions that require immediate action; but in such emergencies I consider dextrose and insulin in the toxic liver and the advice of an experienced surgeon in an acute purulent infection are decidedly preferable to any other procedure. Accordingly the patients here mentioned as treated with curcunat belong to the group of biliary diseases in which medical advice is sought because of persistent abdominal discomfort associated with slight recurrent jaundice

TYPICAL CASES

Case 1—A male teacher aged 37; married with two healthy children Except for typhoid fever 10 years ago the previous history is negative For the past 4 years sensation of fullness in the upper abdomen, beginning about an hour after meals, acid eructations occasionally, no definite relation of symptoms to the type of food, no vomiting, periods of much discomfort alternate with intervals of relief For the last 2 years very severe unilateral headache (right side) has been associated with the abdominal symptoms He said he had often observed yellow discoloration of the scleræ before and during periods of more pronounced discomfort No colicky pain, stools not discoloured, urine not observed

Physical examination—Nov 22nd, 1933 slight jaundice, more noticeable in the scleræ and on the soft palate The whole upper abdomen was tender on palpation, liver not enlarged, but very tender on pressure, much hyperæsthesia of the skin along the right costal arch Urine much urobilin Radiography gastro intestinal tract normal Cholecystography with oral tetragnost no gall bladder shadow After 5 days intravenous cholecystography no gall bladder shadow

Treatment—Animal fat, fried meat, and cabbage forbidden Curcunat dragées, beginning with 3 daily for three days, then 6 for four days, then 8 for two weeks

Progress—Patient went to work as usual, no rest After three days he states that he feels perfectly well The sixth day the jaundice has disappeared The twelfth day no more tenderness of the abdomen Radiography (Feb 4th, 1934) Cholecystography with oral tetragnost gall bladder shadow normal in size, position, density, shape, and reaction to fatty meal Up to July, 1936, no more discomfort except on one occasion, when after a heavy meal he had a bad headache and moderate pain in the right epigastrium, radiating to the back He took again 3 dragées daily of curcunat for a few days, after which he discontinued the medication, the symptoms having subsided immediately

Summary—Chronic cholecystitis with jaundice of 4 years' duration, and hemicrania of 2 years' duration. No filling of the gall bladder on either oral or intravenous cholecystography After treatment with curcunat and slight dietary restrictions, but no other therapy whatever, complete relief lasting two years at present Normal filling of the gall bladder shown by cholecystography 6 weeks after beginning of treatment

CASE 2—A married woman aged 25, no children Previous history negative For the past two years, off and on, distension in the upper abdomen and tendency to constipation, no vomiting, occasional, stabbing pain in the right upper abdomen, radiating to the back No jaundice observed Previous diagnosis colitis No result from the dietary treatment used

Physical examination—Jan 8th, 1935 healthy looking young woman No jaundice Liver moderately enlarged, a little harder than usual Circumscribed tenderness in the region of the gall bladder, no definite hyperæsthesia of the skin Temperature 100 2° F Jan 10th no gall bladder shadow on oral cholecystography Jan. 16th no gall bladder shadow on intravenous cholecystography

Treatment—Animal fat, cabbage, and fatty dressings forbidden Curcunat 3 dragées daily for two days On the second day much discomfort and stabbing pain in the right side Gradual increase of the medication until, after 3 weeks, 8 dragées are taken daily

Progress—Symptoms subsided entirely by the end of the first week About the middle of the third week pain in the right side associated with nausea and dizziness Close questioning reveals that she had eaten sardines preserved in oil the night before the discomfort began consequently all kinds of preserved foods were forbidden Feb 25th no more symptoms, no tenderness of the abdomen, liver no longer enlarged Oral cholecystography gall bladder shadow very dense normal in size and in reaction to fatty meal May 5th 1935 has been in perfect health ever since

Summary—Chronic cholecystitis subsiding rapidly after curcunat treatment The cholecystographic gall bladder shadow, absent before treatment, became normal 6 weeks after beginning of therapy In July, 1936, she had been free of symptoms for 15 months

CASE 3—A merchant aged 54 years Typhoid fever, amœbic dysentery and possibly Weil's disease during the Great War Since 1919 occasional diarrhœa Since 1921 irregular periods of abdominal discomfort with acid eructations, great distension, and sense of fatigue He was told by his family that his eyes were occasionally yellow Because of these symptoms the appendix was removed in 1926 After about two years of distinct relief the same symptoms reappeared Treatment with magnesium sulphate, diathermy over the upper epigastrium, and strict diet gave only temporary improvement Has gained weight since 1930, discomfort increased since Recently an attack of colicky pain in the right upper abdomen Operation therefore advised

Physical examination—April 16th 1935 patient of the short, stout, fat type, looks rather pale, distinct jaundice of the scleræ Much tenderness in the region of the liver, which was not distinctly palpable owing to muscular resistance, spleen very hard, moderately enlarged, descending colon cord like Urine traces of bilirubin, much urobilin Proctoscopy nothing abnormal Radiography descending duodenum greatly displaced towards right, angulated, tender on pressure String shaped appearance of the transverse colon No filling of the gall bladder on oral cholecystography

Treatment—Animal fat, cabbage, fatty dressings and all preserved foods forbidden Curcunat dragées, beginning with 3 daily, gradually increasing to 6 daily

Progress—Very acute aggravation of the symptoms on the second day, since then rapid improvement On discontinuing the medication, however, the patient again felt fullness and distension, he therefore got so used to the preparation that he has been taking it continuously for more than a year past Except for occasional diarrhœa he had not complained of any discomfort up to July, 1936, 14 months after beginning treatment

Summary—Chronic cholecystitis with slight jaundice Spastic colon as a residue of long past intestinal infections Symptoms subsided after curcumin treatment Has taken curcunat regularly for 14 months without feeling any ill effects

RESULTS OF TREATMENT

These are examples of the group of gall bladder diseases that have been treated with curcunat In every instance, but with slight variations, the history, physical findings, and röntgen findings were similar to those described above All the patients were treated in the same way—namely, very slight dietary restrictions, oral administration of curcunat for three weeks in increasing doses, no other therapy, no rest More or less definite aggravation of the symptoms was often observed during the second or third day of this treatment, but relief was almost invariably obtained after about a week. In many instances the symptoms recurred after several months, the patients have then been treated as before and with similar results It was not possible to follow up all of the patients so treated, but a large number were under observation for 2 years or more Of the 67 patients thus treated only one did not improve at all this one was operated upon after a few weeks and a shrunken gall bladder full of pus was removed. With this single exception all the patients were completely relieved throughout periods of observation lasting from 3 months to over 3 years No ill effects were observed or reported, even when the medication was continued for many consecutive months

In 18 cases cholecystograms were made before and after treatment, in all of them the gall bladder shadow was found either absent or very faint before treatment but of normal density afterwards Of course the absence of filling does not prove cholecystitis, nor does a normal shadow exclude it But if a non filling gall bladder appears normal with subsiding clinical symptoms, this finding, however dubious it may be in itself, is an objective confirmation of the clinical observations In this connexion it is of real interest to note that no filling was obtained before treatment, after either oral or intravenous administration of the cholecystographic dye whereas after treatment the gall bladder filled normally on oral ingestion

Since curcunat dragées contain not only curcumin but also calcium cholate the result of the treatment might be ascribed to the latter but the experiments mentioned at the beginning of this article as well as the Röntgen observations on intravenous injection of solutions of pure sodium curcumin prove conclusively that this pigment alone acts as a powerful cholagogue and choleretic in man and in animals Similar pharmacological effects have not been shown after giving calcium cholate in the doses used here It seems quite possible however that the therapeutic effect of curcumin is increased by the addition of calcium cholate, for it is well known that cholates increase and accelerate the intestinal absorption of a number of drugs

CONCLUSIONS

The demonstrable mechanism underlying the clinical results consists in the passage of curcumin through the liver and in the considerably increased flow of bile that it produces Emptying of the gall bladder a less constant factor may increase the effect. These principles apply to almost all forms of therapy known to improve or cure biliary infections. Decongestion of the liver mechanical elimination of infectious material by the increased flow of bile and antiseptic qualities have been considered responsible for the therapeutic effects observed Curcumin clearly acts similarly its effect however seems to me to be superior in chronic cholecystitis to most of the drugs used in this group of diseases For reasons already mentioned I have not treated with curcumin such acute complications as hydrops of the gall bladder purulent cholecystitis and cholangitis or ascending hepatitis In a number of recent publications satisfactory results are reported from the intravenous injection of curcunat in these conditions and since this has proved to be a perfectly innocuous drug intravenous administration may be tried in such complications if the condition of the patient justifies the experiment In general however the effect of a single mode of medication can hardly be ascertained in these cases as the severity of the illness calls for numerous therapeutic measures the results of which become superimposed and correlated

For the appropriate oral treatment the following method may be recommended: First second and third days 3 dragées daily after meals Fourth to seventh day 5 dragées daily Seventh to twenty first day 8 dragées daily The medication can be increased and prolonged if necessary

SUMMARY

Intravenous injection of curcumin the pigment contained in turmeric, produces considerable increase of the flow of bile and—but not constantly—rapid emptying of the gall bladder Curcumin passes through the liver into the intestines and is eliminated by the kidneys after either intravenous or oral administration Clinically oral administration of preparations containing curcumin shows remarkably good results in chronic cholecystitis In this series of observations these results were obtained by oral administration of curcunat under very slight dietary restrictions without any other therapy and in ambulant patients The clinical observations have been confirmed in 18 cases by radiography before and after treatment Ill effects have not been seen It seems justifiable therefore to conclude that the treatment with curcunat is a valuable contribution to the therapy of chronic cholecystitis and allied diseases

THE ANTI CURARE ACTION OF SUBSTANCE 36

CLOSELY RELATED TO PROSTIGMIN

By Grace Briscoe, M.B Lond.

(From the Physiological Laboratory London (R F H) School of Medicine for Women)

ALTHOUGH the antagonism between curare and eserine is well known its exact mechanism has not been settled The resemblance between mild curare-poisoning and myasthenic weakness is close, but it must be remembered that their identity has not been proved. This resemblance has led to the administration of eserine and its analogues to cases of myasthenia gravis One analogue Prostigmin has been used successfully for the temporary alleviation of symptoms (Walker 1934 1935) and shows the same antagonistic action to curare as eserine Another analogue Substance 36 * has given an anti-myasthenic effect almost as good as that of prostigmin (Laurent 1936) but according to Aeschlimann and Reinert (1931) it has no anti-curare action. This discrepancy appeared to add to the problem another factor—how to explain the action of a drug which could relieve one condition and not the other It will be shown that this added complication is unnecessary

The matter is one of some clinical interest There might well be hesitation in using a drug which differed in one important particular from the rest of its group Dr Laurent informs me that he has used the drug for many months and that in some respects it has distinct clinical advantages over prostigmin It can be given in larger doses up to 2 5 mg subcutaneously without atropine Although its initial effect is less than that of prostigmin its action is more prolonged and it is therefore valuable for nocturnal administration. Patients who suffer from insomnia and nocturnal dyspnœa wake up in a more comfortable condition after an overnight dose of Substance 36 for they are still partly under the influence of the drug.

PRESENT INVESTIGATION

Aeschlimann and Reinert used changes of threshold to test antagonism It seemed worth while to test for antagonism by experimental methods already described for curarine and prostigmin (Briscoe 1936)

---

* Methyl phenyl-carbamic ester of 3-oxyphenyl trimethyl ammonium methyl sulphate is Substance 36 in Aeschlimann and Reinert's nomenclature Prostigmin differs only by the substitution of another methyl group for the phenyl group I am indebted to the makers Roche Products Ltd., for a supply of Substance 36 which is not on the market

Different rates and strengths of stimuli are used and changes in shape and size of the myograms noted following administration of drugs

The test muscle is the quadriceps of the cat, in situ with circulation intact The femur is fixed in a vertical position and the movement of extension of the knee recorded by a thread attached to the patellar tendon The cut nerve is stimulated by neon lamp discharges, which can be readily controlled both in strength and frequency (Briscoe and Leyshon 1929)

Large doses of Substance 36 cause characteristic depressant effects in that fast rates of stimulation produce smaller responses than slow rates—that is normal grading is reversed The fast rate myograms are not maintained but become twitch like especially with strong stimulation The shape of the initial curve of contraction is also altered, giving a notched effect These changes are almost the same as those seen in prostigmin and eserine depression (Briscoe 1936)

Antagonism between curarine and Substance 36 has been shown in each of nine experiments It is immaterial which drug is given first

Substance 36 preceding curarine—The depressant effects of Substance 36 can be counteracted by a moderate dose of curarine Complete restoration of the myograms is difficult to achieve, but a constant result has been the return to normal grading—i e, fast rates again cause larger contractions than slow rates Fig 1 shows reversals in magnitude of contraction The notched effect produced by Substance 36 is almost obliterated 40 seconds after injection of curarine The effects of Substance 36, unless antagonised by curarine, can be traced in the myograms for several hours after injection

Curarine preceding Substance 36—(*a*) In a lightly curarised animal the responses to a fast rate of stimulation (150 per sec) give way much more rapidly than in the normal animal, resembling closely the myograms seen in myasthenic patients (Pritchard 1933) A dose of Substance 36 (0 5 to 0 75 mg per kg) injected intravenously causes a quick recovery and the myogram is restored in a few minutes (Fig 2) A similar degree of recovery due to gradual elimination of curarine would take an hour or more, as shown by control experiments (*b*) Recovery from a dose of curarine sufficient to cause a temporary paralysis is hastened by Substance 36 In three control experiments with paralytic doses the intervals between the injection of curarine and the reappearance of ability to maintain a contraction for 5 seconds (in response to maximal stimuli at 30 per sec) were 51, 40, and 44 minutes When a dose of Substance 36 was given during paralysis this stage of recovery was reached 20 minutes after injection of the curarine.

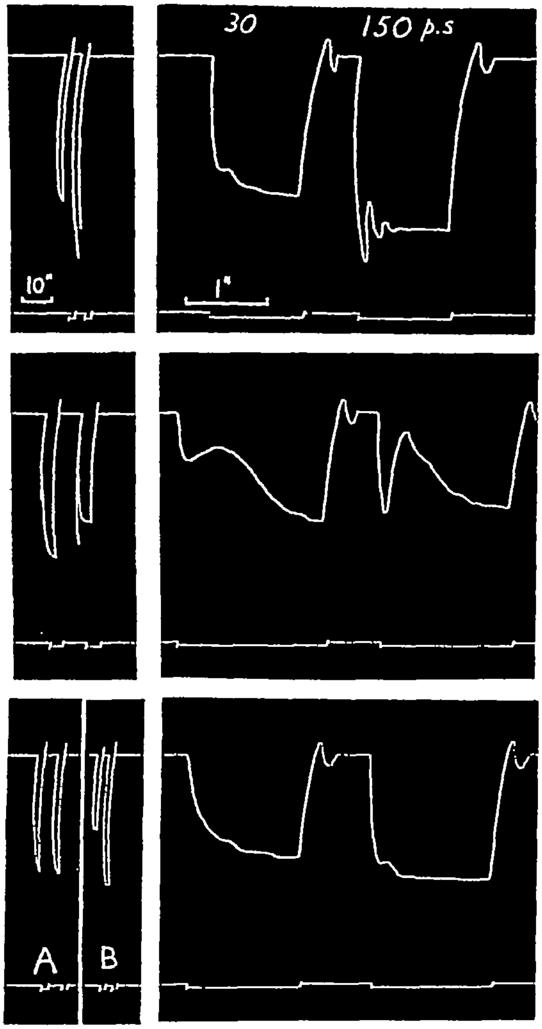

FIG 1—Cat Quadriceps Dial Contraction is downwards in all tracings Submaximal stimuli at 30 and 150 per sec shown first on slow drum then on quick In each case the slow rate precedes the fast rate

Top row—Controls in normal muscle

Middle row—Effect of 1 5 mg per kg of Substance 36 Grading reversed and well marked notches (With supramaximal stimuli 150 per sec produced twitchlike responses and no plateau formation) Slow drum record taken 8 minutes and quick drum record immediately before giving curarine (0 2 mg per kg)

Bottom row—Slow drum (A) 20–30 sec after curarine injection Contractions equal and notch effect less marked (B) 1¼ min later Return to normal grading Quick drum 40 sec. after injection of antagonising dose The response to 150 per sec is already larger than the response to 30 per sec and the notches have nearly disappeared

DISCUSSION

By using the experimental methods described the antagonism of curarine to Substance 36 is shown to

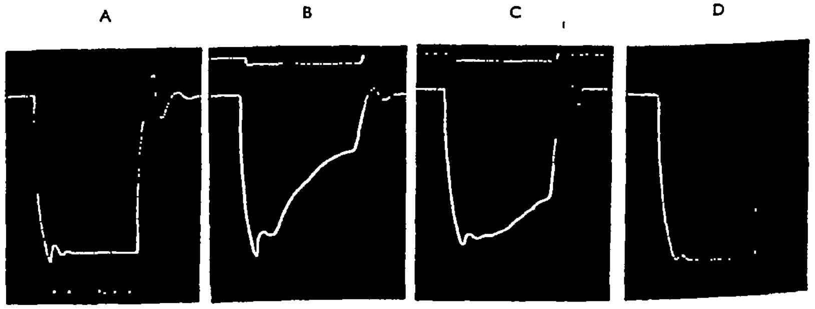

FIG 2—Quadriceps Stimuli submaximal at 150 per sec Time in fifths of seconds

(A) 12 10 P M Control curve of normal muscle 12 11 P M Curarine 0 1 mg per kg intravenously Progressive deterioration shown in records taken each minute

(B) 12 23 P M Effect of light curarisation Tension not maintained Rise of signal denotes cessation of stimulus 12 24 P.M Substance 36 (0 5 mg per kg) intravenously

(C) 12 26 P M Less depression

(D) 12 33 P M Nine minutes after injection Tension maintained be as definite as is its antagonism to eserine and prostigmin The three drugs can be grouped together as far as their reactions to overdosing and curarine are concerned

The failure of Aeschlimann and Reinert to detect antagonism may be explained on the following ground as far as can be judged from the single protocol given by them In a cat (2 7 kg) experiment they gave 20 mg of curare, divided into three doses intravenously and produced a paralysis in 18 minutes. Two minutes later 0 5 mg of prostigmin was given and in another two minutes a minimal twitch appeared at 11 34 At 11 15 a dose of 10 mg of curare was given producing paralysis in 10 minutes A dose of 3 mg of Substance 36 one minute later produced no effect but 0 5 mg of prostigmin 26 minutes later was followed in two minutes by the reappearance of a twitch During the interval of 26 minutes there had been a considerable elimination of curare and it is quite possible that a second dose of Substance 36 would have produced as good a result as the prostigmin It is even possible that the muscle was on the point of emerging from the paralysis without the help of any antagonising drug

Some figures obtained in a control experiment of repeated doses of curarine are of interest

At 10 50 0·3 mg per kg of curarine was injected intravenously This did not produce complete paralysis but small twitch like responses At 11 41 a contraction due to a strong slow rate could be maintained for 5 seconds At 11 44 a similar dose was given producing paralysis at once The first twitch like responses reappeared in 24 minutes. A third similar dose at 12 53 again produced paralysis at once and twitches reappeared in response to strong slow stimuli in 20 minutes

It has been noticed repeatedly that a second dose of curarine given after apparent recovery even if half the strength of the first, produces a more profound depression This observation gives an explanation for the success of the first immediate dose of prostigmin in Aeschlimann and Reinert s experiment and the failure of Substance 36 to antagonise the effect of a second dose

During paralysis it is impossible to know the depth of depression and the time when recovery starts It is advisable to use subparalytic doses so that a continuous record of the myographic changes can be maintained

SUMMARY

Substance 36 an analogue of eserine and closely related to prostigmin, has anti-curare properties as well marked as those of eserine and prostigmin An explanation is offered of Aeschlimann and Reinert s failure to detect this antagonism

SPORADIC SALMONELLA INFECTIONS

WITH A CASE REPORT

BY J H. FISHER, M.B Sydney M.R C P Lond.
MEDICAL REGISTRAR AT THE SOUTHEND-ON-SEA GENERAL HOSPITAL

THE salmonella group of organisms contains many varieties which are closely related culturally biochemically and serologically The most recent classification is that of the salmonella subcommittee of the nomenclature committee of the International Society for Microbiology (Salmonella Subcommittee 1934) Clinically however they may be divided into two main groups the typhoid and the food poisoning

The typhoid group contains *Bacillus typhosus* and *Bacillus paratyphosus* A B and C. The type of illness produced by the paratyphoid organisms is very similar to that of typhoid the chief difference being that the course is usually shorter and less severe

Of the many members of the second food poisoning group only a few are to be commonly found as the cause of outbreaks of food poisoning, the remainder being met with only on rare occasions The type of illness usually seen is one of sudden onset with vomiting abdominal pain and diarrhœa. There may be collapse cold sweats and rigors, and herpes and rashes have been noted in certain epidemics Usually the symptoms begin to diminish after a few days but occasionally they persist for several weeks In epidemics and family infections this is the clinical picture usually seen Sporadic cases however occur quite often, and give rise to many different clinical pictures.

Smith (1934) reported two cases of infection with *Salmonella dublin* The first patient a child of 7 months died from meningitis the organism being isolated from the blood and cerebro-spinal fluid The second died with multiple lung abscesses and empyema the organism being isolated from the blood stream and pus from the empyema An examination of the fæces was negative

Kuttner and Zepp (1933) in a paper dealing with sporadic cases of *Salmonella suipestifer* infections in man noted a very varied clinical picture pneumonia arthritis, cystitis, and meningitis being reported Of the 11 cases 10 were due to European suipestifer (*Salmonella choleræ suis* var *kunzendorf*) and 1 to the American suipestifer (*S choleræ-suis*) Boycott and McNee (1936) report a case of septicæmia and meningitis due to American suipestifer Biddle (1930) reports a sporadic case of European suipestifer septicæmia, and many other single cases of septicæmia and cystitis due to *S suipestifer* of both European and American types have been recorded On the other hand Scott (1926) reports four outbreaks of food poisoning due to *S suipestifer* European type with over 100 cases and all showed symptoms of acute gastro-enteritis

Clayton and Milne (1930) report a mass infection of seven out of eight persons who had consumed an infected pork pie due to American suipestifer and all had symptoms of acute gastro-enteritis This contrasts the fairly constant clinical picture in epidemics and mass infections with the varied picture not infrequently seen in sporadic cases

A sporadic case of infection by *Salmonella enteritidis* Gaertner running a course closely simulating [illegible] was reported by Rosher and Wilson ([illegible])

Salmonella aertrycke is the organism most [illegible] responsible for food poisoning in England [illegible] clinical course taken is usually that [illegible] enteritis, although on occasion it has [illegible] to produce a long-continued [illegible] and Henderson (1928) report a [illegible] after an illness of twenty [illegible] acute mania A blood culture taken post mortem was positive for *S aertrycke*

CASE REPORT

The case was a single isolated one, in which we were unable to determine the source of infection

The patient, a man aged 48, was admitted to hospital on August 20th, 1935 Previous illnesses typhoid fever 21 *years ago* The illness commenced suddenly with vomiting, generalised abdominal pains, and diarrhœa 8 days before coming to hospital

On admission he appeared ill He was drowsy and complained of severe frontal headache The vomiting and abdominal pains had ceased, but the diarrhœa persisted for a few days His tongue was coated with a dry brown fur The abdomen was distended and tympanitic, but there was no tenderness, and the spleen was not palpable An examination of the chest, heart, and nervous system revealed no abnormality The pulse rate was 92 and temperature 101° F

Investigations—The urine was clear The stools were very relaxed, but no abnormal organisms were found in repeated examinations The leucocyte count was 8000 Agglutination tests showed weak agglutination with the salmonella group suspension Blood culture, taken the day after admission, was positive for *S aertrycke* (*Salmonella typhi murium*) The patient's serum 8 days later agglutinated *S aertrycke* in a dilution of 1 in 2500

Progress—The diarrhœa ceased 2 days after admission and did not recur The temperature remained high and continuous for 9 days, coming down by crisis During this time his general condition became gradually worse, and no improvement was shown with the fall of temperature He developed severe pains in the shoulders and lower cervical spine, which were persistent and unrelieved by salicylates He became mentally confused and lost sense of time and place, and he was doubly incontinent The urine was found 18 days after admission to contain large quantities of blood and pus, and on culture *S aertrycke* was isolated

On the 27th day after admission the temperature, after having been normal for 18 days, rose again to 101° F, and varied between 101° and 102° F for a week, gradually returning to normal after 15 days A blood culture was done and *S aertrycke* isolated Agglutination tests showed agglutination of *S aertrycke* (specific) in a dilution of 1 in 2560, and of the group suspension in 1 in 5120 The organism isolated from the blood stream was agglutinated by the patient's serum in a dilution of 1 in 640 An examination of the nervous system now revealed much exaggerated knee jerks and ankle jerks, and a double extensor response The reflexes of the upper limbs were normal The abdominal reflexes were sluggish but all present Owing to the patient being so very ill only a superficial examination of the sensory system was obtained, but no abnormality was detected The temperature fell by lysis and became normal 42 days after admission, after when the patient gradually began to improve, and was discharged to a convalescent home 125 days after admission The urine showed the presence of *S aertrycke* for 3 months, but three specimens examined later at monthly intervals were negative

Result—The patient now 14 months after the onset of the infection, feels quite well, and his only complaint is that he is not quite so strong on his legs as before his illness The knee jerks and ankle jerks are still much exaggerated, and there is a double extensor response The reflexes of arms are normal and abdominal reflexes are present The blood Wassermann reaction is normal, and the cerebro spinal fluid normal in all respects

SUMMARY OF UNUSUAL FEATURES

(1) The length of duration, 4 months and severity of the illness

(2) The failure to find the organism in repeated examinations of the fæces

(3) The isolation of the organism from the blood stream at the commencement of the illness, and again 27 days later, when there was a secondary rise of temperature after it had been normal for 18 days The invasion of the blood stream in both cases was transitory, as examinations repeated in each case 2 days later were negative

(4) The invasion of the urinary tract, and persistence of the organism in the urine for 3 months

(5) Arthralgia of shoulders and cervical spine

(6) The neurological signs—weakness of the legs with increased deep reflexes and double extensor responses, the arms being unaffected—suggesting a myelitis

COMMENT

These invasive clinical pictures, where the course taken resembles typhoid fever, are seen only amongst the sporadic cases, and it is therefore important to consider the factors which may give rise to a sporadic case, and which, if any, of these factors could be responsible for the unusual clinical pictures so often seen.

The factors which might give rise to a sporadic case are

(1) The patient may have eaten more of a particular dish than the rest of the family

(2) The bacilli might be distributed unequally in the food

(3) The alimentary tract might be less resistant, possibly due to a previous infection of gastro enteritis

(4) The patient may be specially susceptible to the organism

(5) The resistance of the patient may be lowered by some factor—for example, an operation, with activation of latent bacilli

Cases have been reported following operations Biddle (1930) reports a case of *S suipestifer* septicæmia discovered in a patient six days after an operation for a ruptured ectopic gestation Küttner and Zepp (1933) report a case of *S suipestifer* septicæmia and cystitis occurring in a patient following a radical antrum operation Elkeles and Standfuss (1931) explain the rare cases following operation as being due to an activation of latent bacilli in the bowel Increased dosage or increased virulence of the organism cannot be the explanation of the more invasive clinical pictures, as they should then occur also in the epidemic cases

An individual hypersusceptibility might explain both the sporadic nature of a case and also the unusual invasive clinical picture However, if this were the true explanation, a proportion of such hypersusceptible individuals should be amongst those attacked in epidemic outbreaks

A lowering of the resistance of the patient, with activation of latent bacilli, would explain both the sporadic nature of the attack and the varied clinical picture

The resistance of the patient being low, the organism quickly enters the blood stream, and may invade the bladder, meninges, lungs, or joints without in many cases attacking the gastro intestinal tract There is also the possibility that organisms which have been lying latent in the body may, as the result of time and adaptation to an altered environment, become more virulent, and so resemble in their invasive properties the closely related typhoid and paratyphoid members of the group An activation of latent bacilli would also render the determination of the original source of infection impossible, and the difficulty of finding the source of infection is a characteristic feature of sporadic cases

As noted by Smith, it appears that of the salmonella organisms commonly met with *S dublin* and *suipestifer* are much more frequently the cause of septicæmic manifestations than are *S enteritidis* Gaertner, *S thompson*, and *S aertrycke* The case of aertrycke infection described here however, in its course and complications, resembled a severe typhoid infection, and it appears that any of these closely related *organisms may under certain conditions invade the* blood stream and give rise to any of the symptoms or complications seen in infections by the typhoid group

SUMMARY

1 The clinical picture in sporadic salmonella infections is very variable, and cases where the organism invades the blood stream and the course taken resembles *typhoid fever are not uncommon*

2 This contrasts with the fairly constant clinical picture of gastro-enteritis seen in epidemics and family infections

3 A sporadic case of *S aertrycke* infection is described, in which the illness resembled a severe case of typhoid fever

4 A lowering of resistance with activation of latent bacilli is suggested as an explanation of the typhoid like illness seen in some sporadic cases It is also possible that the bacilli as a result of time and adaptation to an altered environment become more virulent, and so resemble in their invasive properties the closely related typhoid and paratyphoid members of the group

5 Cases following operations support this explanation

6 *S dublin* and *suipestifer show a much greater* tendency to undergo this change than do the other members of the group commonly met with—*S enteritidis* Gaertner *thompson* and *aertrycke*

I desire to express my thanks to Dr A. B Rosher for his assistance in the bacteriological investigations involved and to Dr J G Leebody medical superintendent of St George-in-the East Hospital for his permission to publish the case

HERNIO-APPENDICECTOMY

BY JOHN T MORRISON O.B E F R C.S
HONORARY SURGEON ROYAL SOUTHERN HOSPITAL, LIVERPOOL
LECTURER IN CLINICAL SURGERY UNIVERSITY OF LIVERPOOL

MORE than one attempt has been made to devise an extraperitoneal approach for the radical cure of hernia. The most successful is probably Lotheissen's operation for femoral hernia. A. K Henry (1936) has described a midline incision for dealing with both femoral and inguinal herniæ by the extraperitoneal route which he claims may be used effectively even in difficult cases

It is likely nevertheless that the Bassini operation or some modification of it will remain the operation of choice for inguinal hernia in persons over 25 and in all complicated cases In children on the other hand and probably in young adults all that is necessary is removal of the sac the whole sac and nothing but the sac If one were to propose any departure from these well established principles it would be necessary to show that the innovation was equally innocuous, equally efficient and, further that it provided some specific advantage not to be attained by the more orthodox methods The operation about to be described has been confined so far in the main *to children over 2 and young adults, and* I do not at present feel inclined to advocate its extension to older patients or complicated cases In the hands of those accustomed to operating on young children I see no reason why the procedure should not be carried out more often at an even earlier age

The position of the internal ring is identified just above Poupart's ligament midway between the anterior superior spine and the middle of the crest of the pubis A finger's breadth above the ring the usual oblique incision is made in length perhaps 1½ inches The external and internal oblique muscles are split in the line of their fibres the lower border of the transversalis usually lies at a higher level and can be hooked up out of the way The extraperitoneal tissues are now reached and the rounded bulging edge of that membrane can be seen giving off a process which passes at once into the internal abdominal ring This is of course the hernial sac It is picked up with forceps and carefully cleaned as in any other operation for hernia. It should be noted *that in young children even a small amount of pull* on the sac with its attached cord may drag the testis up into the canal After one's manipulations are completed in these little patients one ought to make certain therefore that the testis has not been displaced.

The cleaning of the sac is begun on the inner side and here lying well to the back will be found the vas deferens to the outer side of which behind the sac, are placed the spermatic vessels The isolated sac is cut across, the distal end neglected, and the edges of the proximal opening secured with forceps If necessary the peritoneal aperture may be enlarged. It is usually easy to secure the cæcum with Duval's forceps but if it fails to appear it can be identified with the finger and so captured. The appendix, if normal, can then be removed but if adhesions give rise to difficulty I *consider one is amply justified* in enlarging the muscle wound to give proper access to the iliac fossa. At the end of the operation the peritoneum is closed the internal oblique drawn together with a single stitch and the external with two

It can be claimed, with confidence I think that the three considerations needed to justify an innovation of this kind have been satisfied There could hardly be any procedure less injurious to the abdominal wall, and although I would hesitate to make claims for its infallibility it is theoretically sound I can only state that during the ten years or more during which I have practised it I have not seen or heard of any suggestion of recurrence The specific advantage gained is of course easy access to the appendix without unduly prolonging the operation or prejudicing its success In this connexion it should be mentioned that Torek in 1906 *urged that* when in the right inguinal region the surgeon should take the opportunity of removing the appendix and others following him have supported this view They point out—and in my earlier cases I took pains to confirm this observation—that the appendix is abnormal in a surprising proportion of cases. Even more important however is the problem of prophylaxis. Every surgeon I think, is agreed that when in the course *of an operation* the appendix can be removed without detriment to the patient this should be done The operation just described claims to bring radical cure of hernia in certain cases into the category of such operations

In Torek's procedure an extension of the hernia incision was made in an upward and outward direction to enable the surgeon to make a small gridiron opening through the muscles and so remove the appendix It was a gridiron appendicectomy superimposed on whatever type of herniotomy the surgeon might favour In the procedure I describe the approach to the appendix is an integral part of the radical cure

SULPHÆMOGLOBINÆMIA FOLLOWING SULPHANILAMIDE TREATMENT

By George Discombe, B Sc Lond.

JUNIOR DEMONSTRATOR OF CHEMICAL PATHOLOGY ST BARTHOLEMEW S HOSPITAL, LONDON

Prontosil Album and other brands of sulphanilamide (which is another name for *p* aminobenzene sulphonamide, *p* aminophenylsulphonamide, or sulphonamide P) have been used generally for some months Trefouël and others (1935) and Fuller (1937) have shown that the soluble red azo dye Prontosil Soluble (for injection) and the almost insoluble orange azo dye Red Prontosil (oral) are bactericidal only after reduction to sulphanilamide For this reason, and to avoid the pain associated with the injections of prontosil soluble, many workers have used sulphanilamide alone, which can be taken by mouth.

At first this substance was believed to be non toxic later it was found to produce occasional cases of sulphæmoglobinæmia (Colebrook and Kenny 1936a, three cases, Foulis and Barr 1937, two cases, Thomas 1937, Frost 1937, one case each) Frost did *not use sulphanilamide, but prontosil soluble and* N benzyl sulphanilamide (Proseptasine) on which no other clinical reports have so far been published The impression given by these three papers is that sulphæmoglobinæmia may be an occasional complication *of sulphanilamide treatment,* but that it is unusual

When one case of extreme cyanosis following sulphanilamide was recognised at St Bartholomew's Hospital, all patients who were receiving, or who had recently received, that substance were carefully examined Of seven patients who had received over 5 grammes, six showed some degree of sulphæmoglobinæmia, three showing marked cyanosis All these patients received the Prontosil brand of sulphanilamide It appears that sulphanilamide is one of the most active drugs for the production of sulphæmoglobinæmia at our disposal

Of these seven patients, four (*Nos 1, 2, 3, and 4*) received frequent doses of magnesium sulphate, two of these (Nos 1 and 4) developed cyanosis, while two (Nos 2 and 3) showed a less degree of sulphæmoglobinæmia One patient (No 5) who developed cyanosis received only two doses of magnesium sulphate, and one (No 6) which received no magnesium or sodium sulphate by mouth, but who did have dressings of sodium sulphate on a large gangrenous area, developed a very slight sulphæmoglobinæmia The one patient (No 7) who did not show any abnormal pigments in the blood, in spite of long continued sulphanilamide treatment had no sulphates by mouth or as a dressing during the treatment None of the patients affected has died all are recovering

CASE REPORTS

Case 1 —Mrs A aged 31 Panophthalmitis multiple streptococcal abscesses following lobar pneumonia Admitted on Jan 1st, 1937, having had prontosil album for three days previously Between Jan 23rd and Feb 15th received a total of 41 4 grammes of sulphanilamide, or 1 8 g daily Between Jan 26th and Feb 5th received also 85 c cm prontosil soluble, or 2 125 g Received magnesium sulphate at irregular intervals during this period On Feb 15th cyanosis of *the lips and finger* nails was observed and on the 18th this was shown to be due to sulphæmoglobinæmia The appearance of the *patient at this time* was characteristic, *the lips and nail beds a cold blue, the face* very pale, the blood even after shaking with air, remained a deep brown It was indeed surprising to find her cheerful and talkative, not in the least worried or inconvenienced by her condition No quantitative estimation was possible at this time, but the strength and persistence of the α band of sulphæmoglobin suggested that at least 40 per cent of the hæmoglobin present was in that inert form

Case 2 —Miss B, aged 19 Mastoiditis, Schwartze operation Received 16 2 g sulphanilamide between Feb 9th and 19th (1 8 g *daily*) *Magnesium sulphate* was given irregularly between Feb 1st and 16th On the 19th a faint band due to sulphæmoglobin was seen in the *patient's shed blood* There *was no* cyanosis *and* she left hospital on the 20th

Case 3 —Miss C, aged 20 Lupus erythematosus, suspicion of pulmonary tuberculosis Between Feb 3rd and 18th received 27 g sulphanilamide (1 8 g daily) Magnesium sulphate was given irregularly during this period On Feb 18th the α band of sulphæmoglobin was observed in the patient's shed blood It was stronger than that shown by Case 2, but there was no cyanosis

Case 4 —D E, aged 21 Mastoiditis, Schwartze operation, lateral sinus thrombosis, osteomyelitis resection of the third right costal cartilage Between Feb 4th and 18th received 25 2 g sulphanilamide (1 8 g daily) Magnesium sulphate was given daily from Jan 31st until Feb 21st except on the 12th On the 18th obvious cyanosis was present, shown to be due *to sulphæmoglobin by spectroscopic examination on the* 20th In this case the blood showed a brown tint, though less than that from Case 1

Case 5 —Mrs F, aged 51 Streptococcal abscess left thumb Pus contained hæmolytic streptococci Between Feb 13th and 26th received 25 2 g sulphanilamide (1 8 g daily) *On Feb 19th and 21st magnesium sulphate* was given Examination on Feb 22nd had shown no evidence of sulphæmoglobinæmia, yet on the 26th the patient developed cyanosis, almost as severe as in *Case 1* Her blood was brown, even to the untutored eye, and showed an intense α band of sulphæmoglobin On, Feb 13th and *14th* polyvalent antistreptococcal serum had been injected and a serum reaction, with fever and an urticarial rash, developed on the 21st 22nd, and 23rd This may have some relation to the sudden onset of cyanosis

Case 6 —Miss G, aged 15 Gangrene of chest following chicken pox, pus contained hæmolytic streptococci Between Feb 16th and 26th received 18 g sulphanilamide (1 8 g daily) No magnesium or sodium sulphate was given by mouth but sodium sulphate dressings were applied to the gangrenous area On Feb 27th a faint but easily seen, band of sulphæmoglobin was detected in the patient s blood

Case 7 —H I aged 28 Osteomyelitis of the left maxilla *Between Jan 25th and Feb 18th he received* 41 4 g sulphanilamide (1 8 g daily) No magnesium or sodium sulphate was given by mouth or in dressings No sulphæmoglobin could be detected on the 18th or 23rd

Case 8 —J K, aged 10 Mastoiditis Schwartze operation, diabetes mellitus This boy had only 2 7 g sulphanilamide in three days and occasional doses of sodium and magnesium sulphates No sulphæmoglobin was found and this case is not included in the discussion on account of the small total dose and short period of administration

DISCUSSION

The occurrence of sulphæmoglobinæmia in 6 out of the first 7 cases undergoing a moderately long course of sulphanilamide treatment may be fortuitous it seems far more probable that it represents a genuine correlation and that the occasional frank cyanosis is due to a quantitative rather than qualitative difference in the action of the drug. The results presented here neither confirm nor deny the suggestion (Colebrook and Kenny 1936a, following van den Bergh and Revers 1931) that there is some connexion between magnesium sulphate and the development of sulphæmoglobinæmia in sulphanilamide treated patients It is hoped that in the near future it will be possible to present a series of cases treated with sulphanilamide which *have had no sulphates either by mouth or as dressing*

The cyanosis caused by sulphæmoglobin is spectacular and alarming but fortunately it does not produce any very serious consequences if the drug is stopped as soon as it is noticed in the three cases *described here the patients were annoyed when attention was drawn to their condition but not in* the least perturbed The only troublesome consequence is that the stay in hospital may be prolonged All these three had fairly high hæmoglobin figures *the lowest being 48 per cent This condition may* be dangerous however if the total hæmoglobin percentage falls below about 30 per cent (Haldane scale) for then cyanosis cannot occur and the drug responsible for the sulphæmoglobinæmia may be continued until *over half the total hæmoglobin* present is changed to the inert form the plight of a patient with a streptococcal infection and about 15 per cent. active hæmoglobin may easily be imagined.

For this reason it is impossible to regard a careful watch *for cyanosis as a sufficient precaution* The *total hæmoglobin should be determined and the* patient s blood should be examined regularly at intervals of less than four days (cf Case 5) It is best to examine the shed blood, diluted with water or ammonia *but quite small quantities of sulphæmo*globin can be detected by examining the blood in the lobe of the ear using a torch and direct-vision spectroscope as described by Harrison (p 204) The necessary skill may be acquired by a little practice

*There can be no doubt that in these cases sulphæmo*globin not methæmoglobin was present It is found that dilution of blood with 0·4 per cent ammonia destroys the α band of methæmoglobin but does not affect that of sulphæmoglobin all *specimens of blood* were examined in water and in 0·4 *per cent ammonia One or more other tests* were made on each blood ; persistence of the α band on treatment with reducing agents (ammonium sulphide sodium hydrosulphite) shift of the α band towards the violet on treatment with carbon monoxide matching the α band in the Hartridge reversion spectroscope with that of sulphæmoglobin artificially prepared from normal blood One sample of blood was submitted to all these tests by Dr G A Harrison (Case 1)

Thanks to the work of Tréfouel et al (1935) Colebrook et al. (1936) Fuller (1937) and others referred to in their papers some knowledge is being obtained as to the mode of action and suitable uses of sulphanilamide So far its advantages seem heavily to outweigh its dangers and its use is being limited and extended as more knowledge is obtained. It is *however very important to be alert to all possible* complications and the possibility of grave anoxia due to unrecognised occurrence of sulphæmoglobinæmia should be borne in mind while still more information is available the administration of magnesium or *sodium sulphate* to sulphanilamide treated patients should be forbidden

SUMMARY

(1) Sulphæmoglobinæmia is a commoner consequence of sulphanilamide treatment than has hitherto been recognised (2) Sulphæmoglobinæmia is dangerous to anæmic patients (3) Regular *spectroscopic examination of the blood of all patients* receiving sulphanilamide is therefore advocated.

My *thanks are due to those members of the honorary* staff of St Bartholomew s Hospital, Prof J Paterson Ross Dr A. C Roxburgh Mr Sydney R Scott and Mr R Foster Moore who have given me permission to publish details of their cases to their house surgeons to Dr G A. Harrison and Dr H E Archer for their advice and assistance and to the nursing staff, especially to Miss Capon.

Clinical and Laboratory Notes

COMA AS THE FIRST SYMPTOM OF DIABETES

By E Fretson Skinner, M.D Camb
F R C.P Lond
PHYSICIAN TO THE SHEFFIELD ROYAL HOSPITAL

DIABETIC coma in spite of insulin is very often fatal and usually presents difficulties The case to be described may be of interest because it showed one feature that I had always considered a sign that death was certain—namely commencing anuria—but *nevertheless* ended in recovery

So far as could be ascertained the patient s symptoms began on Thursday May 30th with headache and vomiting which were ascribed to dietary indiscretions by her medical man ; he ordered a simple laxative régime Nothing unusual happened until *the following* Tuesday afternoon (June 4th) when a kind *of delirium set in and the* doctor was sent for again She was a woman of 28 *the age sex, and various other circumstances* suggested a diagnosis of hysteria, but he was not satisfied that this was really the condition As she did not improve he asked me to see her the same evening When I arrived at about 9 P M she was lying in bed semi-conscious and talking nonsense She had a dry cracked tongue dry skin and breath smelling strongly of acetone By this time the diagnosis was clearly one of diabetic coma and she was sent to hospital at once The urine had been examined three days previously when her illness began, and had been found free from sugar and albumin.

When she reached hospital about 10 P M I found the urine (catheter) contained a very large amount of diacetic acid and 8 per cent of glucose A blood sugar estimation, made while the ordinary routine *preliminary* coma treatment of rectal washouts and glucose-saline enemas was being carried out gave a reading of 0·77 per cent (Folin and Wu s method) *As she was still just rousable* hot saline and 10 per cent glucose with 5 per cent bicarbonate of soda was given by mouth almost continuously and her nurse *was instructed that she must be made to drink at* least three pints of this hot saline before morning At the same time 60 units of insulin was given immediately *to be followed by another 60 units in two hours.* As this did not lessen the depth of coma an attempt was made to give an intravenous glucose saline, but she was a plump girl and the vein could not be found, so a further 100 units of insulin was given intramuscularly, and rectal and oral administration of glucose saline continued.

By the morning she was obviously worse and absolutely comatose, she had stopped passing urine, the temperature was falling (97·2° F.), there was much air hunger with a very slow respiratory rate and the blood sugar content was 0·8 per cent. A vein was exposed and intravenous administration of glucose saline begun. She was given two pints of saline with 10 per cent. glucose and 10 per cent. bicarbonate of soda. The rectal saline was continued by means of a Murphy's drip apparatus and insulin was administered in doses of 100 units every four hours. With the idea of trying to counteract the anuria, radiant heat was applied by means of the ordinary electric lamp bed cage for several hours. By the evening of this the second day in hospital (June 5th) there was a suggestion of improvement, the temperature rose to 97·8° F., the tongue was noticeably less dry and cracked. By the following morning (June 6th) she had begun to pass urine again (750 c.cm. during the 24 hours) and coma gradually lessened. At this time the blood sugar was 0·17 per cent., and during the day she made a complete recovery from coma.

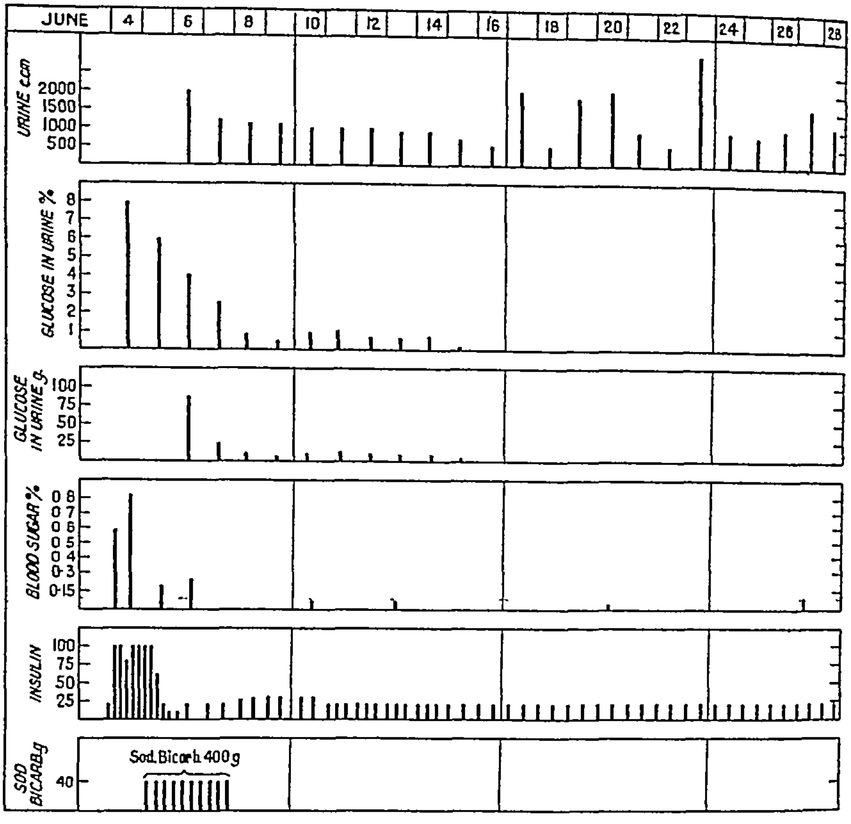

Chart showing the quantities of insulin and sodium bicarbonate given and the changes in secretion of urine glucose in urine and glucose in blood

During the 25 hours of really intensive treatment she received 800 units of insulin; the question of giving pituitrin was discussed but finally answered in the negative.

In an influenza epidemic about the same time I was so unfortunate as to lose three of my old diabetic cases from coma immediately following an attack. Without exception they were all anuric for about 24 hours before death, and the symptom was then impressed on me as a sign of impending fatality. When this symptom appeared in the above case I gave a fatal prognosis to the relatives, and it is of interest to know that the symptom does not necessarily mean that death approaches. We had been on the look out for anuria from the experience in the three previous cases, and as soon as there appeared to be a diminution in the quantity of urine passed the radiant heat was started.

There are one or two points of interest in the case. First of all the fact that diabetes had not been suspected, there having been no previous ill health. Secondly the development of deep coma was extremely rapid, for coma was complete within eight hours of the onset of the first symptoms. Thirdly the blood sugar was very high at the time of deepest coma. I have only once seen a blood sugar value of 0·8 per cent., and this was in an elderly patient who also had chronic granular nephritis and who died of uræmia after recovering from a diabetic coma for a few hours.[1] A further point of interest is the very large dose of insulin given in a few hours. There is no doubt that without insulin this girl would have died, for insulin is the only hope in diabetic coma and even now only becomes a hope if given in sufficiently large doses. The danger of insulin, at any rate in coma cases, lies not in giving too much but in giving too little. The Chart represents the progress of the case for a month, day by day.

The patient now, seven years later, remains well and is doing her work as a checking clerk on the railway. Her diabetes is moderately severe, requiring 30–40 units of insulin daily, and she has been in hospital three times—twice with mild diabetic coma and once with hypoglycæmic coma.

ECLAMPTIC HEMIPLEGIA

By Miron Hajkis, M.B. Oslo, L.M. Rotunda

Eclampsia has been known since Moriceau described it in 1688. The rarity, however, of palsies in the clinical picture of the disease stands in striking contrast to the frequency of intracranial hæmorrhage or of areas of softening in the brain. This was pointed out by Schwanen (1934) who collected 34 cases of paralysis in eclampsia and toxæmias of pregnancy, and described three of his own cases.

The central hæmorrhage is a sudden one and the palsy is soon complete (Talley and Ashton 1925), the coma followed by hemiplegia is profound and tenacious (Brindeau 1927). The mortality is 50 per cent., which seems to be independent of the number of fits but determined by the size of the central focus. The patient's age is of no importance in the prognosis (Schwanen 1934). According to Talley and Ashton only a few of those patients living had permanent palsies left and even those show improvement Other causes of central puerperal palsies more frequent than cerebral hæmorrhage are cerebral thrombophlebitis and sinusitis and cerebral embolism from a septic thrombophlebitis in the pelvis from a thrombosis of lower extremities either frank or concealed or from endocarditis. Brain abscess and purulent meningitis as incidents in general septicæmia may also lead to puerperal palsy Brindeau says that it is usually impossible to diagnose the cause.

---

[1] Imrie, C. G., and Skinner, E. F. (1924) Lancet, i, 14.

The patient was a primipara a strongly built woman aged 37 who had not been ill previously A fortnight before labour she had headache nausea and heartburn as well as increasing œdema of the lower extremities She had not received any antenatal treatment During the labour which was at full term she had 3 series of convulsions, the last of which was just before spontaneous delivery It was violent and was followed by 4 hours of deep coma The child was stillborn

Even at that time while the patient was in coma, the right arm and leg were remarkably flaccid so that it was assumed that hemiplegia was a fact When she recovered consciousness total paralysis of the right upper and lower extremities and paresis of the lower portion of the facial musculature of the right side was observed There were no serious disturbances of speech Eyes and ears normal No rigidity of the back and neck. Kernig s and Brudzinski s sign absent No hyperæsthesia No clinical evidence of tuberculosis.

The rise in temperature 100 4–101 8 F and in the pulse-rate 92–112, was observed for 5 days Œdema of the lower extremities disappeared within a week albuminuria lasted for 3 weeks On the paralysed side the deep reflexes were increased; Babinski s sign present The other superficial reflexes were diminished The sphincters were normal.

The palsy of the spastic type was slow in recovering It was more than a year before the paralysis had become reduced to the permanent state of limited mobility o the right wrist and fingers, and some muscular atrophy of the hand the skin on the dorsum being somewha thin and glossy Patient now complains of sensation of cold in the hand which is rather cool to the touch When working and eating she uses her left hand Sh also complains of paræsthesiæ in the right foot whic becomes quickly tired but there is no paralysis in the leg The facial paresis has completely vanished.

Two years after the labour she had a normal delivery o a living baby and she has otherwise been well

The cause in this case seems to have been a cerebral hæmorrhage, because of the sudden onset of a complete paralysis A cerebral thrombosis or an embolu —e.g from a concealed thrombophlebitis in the pelvis—seems to be less probable. There were no signs of septicæmia or endocarditis, and no clinical evidence of thrombosis of lower extremities The post-partum rise of temperature and pulse-rate must be regarded as a febrile reaction from the cerebral hæmorrhage or the toxæmia.

DeLee (1934) observes that a neurological examination would perhaps reveal a tuberculous or other meningitis instead of that of eclampsia. The investigations carried out in this case, however rule out the possibilities mentioned by DeLee of diseases other than eclamptic hemiplegia.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTIONS OF SURGERY AND RADIOLOGY

These sections held a joint meeting on March 3rd with Prof. G Grey Turner, president of the section of surgery in the chair Mr W Sampson Handley opened a discussion on the value of pre- and post-operative

Irradiation in Malignant Disease

with special reference to carcinoma of the breast He said that post operative irradiation was of most value in preventing recurrence through implantation of malignant cells from the original growth at operation If radium destroyed massive recurrences some time after operation a fortiori radium applied just after the operation would destroy the individual cells from which recurrences grew Deep X rays were probably as effective for this purpose as radium which was known to destroy massive recurrent growths and ought therefore to be still more capable of destroying individual cells Implantation was always a danger and there were very few cases in which it could be disregarded A short course of deep X rays should be given to the operation scar in all cases of gastric intestinal or pelvic cancer as well as after operations for mammary growths and cancer of the cervical glands Alternatively radium tubes could be inserted at the time of operation On the whole he was not in favour of pre-operative irradiation for several reasons It produced a general and local reaction from which the patient must be allowed to recover before operation which was sometimes thus postponed for an undesirable length of time allowing extension of the dangerous deep parts of the growth. The operator could not guarantee that the pre-operative irradiation would affect the whole growth and deep microscopical extensions of it might progress during the interval. Even with modern high voltage X rays it was difficult to give a sufficiently intense deep dose to kill carcinoma cells without damage to the patient s tissues. X rays would often cause the primary growth to regress and become mobile but, as Mr Handley showed by several slides individual cells from the growing edge would still continue to reproduce Intensive deep therapy hindered the surgeon by lowering the patient s vitality Moreover X rays were used to better advantage after the operation because they had not then to penetrate a thick mass of mammary tissue in order to meet the deeper layers such as the intercostal muscles and the pleura Before operation even deep X rays would not deal adequately with the internal mammary and apical axillary glands The internal mammary glands should be treated at operation by interstitial radium and the apical glands should be removed He agreed that it was impossible to make a trustworthy estimate by statistics of the relative merits of pre-operative and post-operative irradiation The best hope for progress in treatment lay in public education to the vital necessity of prompt treatment of suspicious lumps in closer study by radiologists and surgeons of the details of dissemination and in the adoption practically as a routine after carcinoma operations of a short prophylactic course of X rays of at least 180 000 volts

Good results had been claimed for surgical or radiological oöphorectomy but Ahlbom had concluded that radiation castration together with local radiation was no better than local radiation alone in 163 cases observed at Radiumhemmet. The only real value of castration was *to prevent subsequent* pregnancy—a result better achieved by contraceptive methods. Subsequent pregnancy was undoubtedly dangerous; of fifteen cases of pregnancy after carcinoma of the breast, thirteen promptly developed cancer in the remaining breast. Even among radiologists there was division of opinion as to the value of pre-operative radiation. F. E. Adair and F. W. Stewart had tried carefully to assess its value. Thirty-nine patients had been given a radium pack of 4 g. at a skin distance of 6 cm., using four ports, the dose being 20,000 to 44,000 m.c.h. per port. In 28 per cent. the tumour had completely disappeared, and in 13 per cent. no growth had been found in the glands. In 28 per cent. visible cancer had still been present in the breast, and in 73 per cent. in the glands. Forty-two cases had had pre-operative X rays of 200 kv.; the growth in the breast had been destroyed in 16.5 per cent., but the growth in the glands had never been affected. These results did not offer the method much support.

Dr. W. M. LEVITT put the case for a combination of radiation and surgery. In any given series of cases it might be said to be assumed that x cases would be well after five years if treated by surgery and y if treated by X rays. The individuals in either groups would almost certainly differ according to the variation in the factors which made either for radio-sensitivity or for operative success. It was therefore reasonable to suppose that if the two groups of treatment were combined, a more or less complete summation of the successes would be obtained. It had at one time been the common practice in combining the two methods to carry out the radical operation first and regard the X ray therapy as a doubtful safeguard afterwards. Even the radiologist had fallen into the error of being satisfied with a less thorough radiation than he would have given in a case of appreciable disease. Carcinoma cells required a lethal dose, whether the colonies were small or large. Moreover, the X rays had to be distributed over just as wide an area in order to include the whole chest wall and clavicular region on the affected side. Probably owing to under-treatment, post-operative irradiation had not in the past produced spectacular improvement in the published results, although local recurrences had materially decreased. The surgeon was usually in favour of post-operative irradiation; his objections to pre-operative irradiation were those given by Mr. Sampson Handley. The question was whether the irradiation could prevent fresh secondaries and, if so, at what stage in the treatment it was effective. The danger of operating in under a fortnight after irradiation must be offset by the reduction of the danger of implantation and dissemination at the operation. High voltage therapy could convey an adequate dose to the deeper tissues without injury to the superficial tissues, and would also adequately irradiate internal mammary and apical axillary glands, for the hard rays would easily pass through bone. There was definite experimental evidence, in favour of pre-operative irradiation, that irradiated carcinoma cells were less likely to flourish if implanted into a new site at operation and also that they were much less likely to take root in irradiated tissues. Moreover, irradiation caused considerable reduction in the areas of growth through damage to the tumour cells. Irradiated cells, though they might survive, often could not reproduce, and this fact might account for the well-known delayed effect of irradiation. Pre-operative irradiation with maximum doses had in many cases led to sepsis and disaster, so that some reduction in the dosage had been necessary, but this deficiency could be made up by a supplementary course of irradiation as soon as the patient had recovered from the operation. The experience of foreign clinics had shown that this method was safe.

The sooner irradiation was given after operation the better, but it was better to wait until the stitches had been removed. The supplementary course should be given two or three weeks after the first post-operative course. No modification was called for in the radical operation, provided that undue tension on the stitches was avoided. The use of the diathermy knife did not appear to increase the risk. Where only post-operative irradiation was being considered the field was unsuitable for interstitial radium, and X rays were more satisfactory than surface radium, for they gave a more uniform dosage over a wide area. Internal structures could be protected by tangential methods of application.

Pre-operative irradiation might be carried out either by interstitial radium or by deep X ray therapy. The X rays probably gave better irradiation of the apex, axilla, and supraclavicular region. Anæsthesia was unnecessary, but the treatment was more tedious than with radium. Irradiation of an inoperable growth by full doses sometimes made it operable, and the radiologist was often asked whether it was then safe to operate. Dr. Levitt held that it was perfectly safe if a complete radical operation was not contemplated. Removal of the breast was valuable after X ray treatment and should be undertaken wherever possible, even if the growth had completely disappeared and the patient appeared to be perfectly well. A breast which had once been the site of carcinoma was always a menace, by whatever means it was treated. These principles of combined therapy applied to the treatment of malignant disease in any part of the body. Dr. Levitt quoted the results of Coutard, Berven, Holthusen and Holfelder, and compared their practice in combined treatment.

Mr. G. F. STEBBING said that he always began treatment of carcinoma of the breast on the assumption that by irradiation alone he would be able to get rid of the tumour, and that the breast should only be excised when it was realised that irradiation by itself would not be successful. If when the patient was first seen the surgeon decided to operate, pre-operative irradiation could be given for a number of purposes. The first was to reduce the size of the tumour by killing the most radiosensitive cells, which were those most likely to lead to metastases. The second purpose was to render the tumour more mobile by reducing the amount of inflammation in the surrounding tissues. A third was to lessen the vitality of all the tumour cells so that any which were sown on the surface of the wound or squeezed into the lymphatic stream would have less chance of survival. Even a small pre-operative dose was better than none, but it was wiser to give such a dose as would kill off all those cells which could be killed off with the least damage. The best results were obtained by an adequate dose of X rays—in the absence of a radium beam to the breast, axillary and supraclavicular regions. Using 200 kv., some 4500 r should be delivered within three weeks to every part of the patient which was assumed to contain carcinoma cells. Skin reaction would make it necessary to postpone operation for about three weeks, but at the end of that time a radical operation might be performed The interval was well spent and if the tumour and neighbouring lymphatic glands were immobilised and there were no danger of pressure or squeezing the danger of metastases was very small. The healing of the wound was slower and skin grafting would not take for some two months after the operation. Post-operative irradiation should only be given on the assumption that the operation had left behind tumour cells and the operator must decide where they were It should only be employed in the breast region if it was likely to be really effective Local recurrences could be treated easily and successfully by radium The axillary and supraclavicular regions should be given a carcinoma killing dose after every operation for carcinoma of the breast. The term prophylactic should be completely abolished for it tempted to inadequate treatment of an area which should be left alone until disease was present

Dr J R K Paterson said that there were only two main possibilities to which importance should be attached. The radiation should act on sufficiently responsive growths in such a way as to produce lethal change either in the tumour before removal or in isolated fascia or cells of malignant disease after removal Alternatively post-operative irradiation should provide a lethal dosage over an area wide of the operative procedure but have no influence on the field of operation itself Both of these methods depended on the direct effect on the neoplastic cells in the area of irradiation and not upon a systemic effect Pre-operative irradiation might also devitalise malignant cells so that they would not take root if they were scattered, but this was seldom the explana*tion of the effect of pre-operative irradiation as* ordinarily given Either before or after operation irradiation must be given in such doses as were known to produce definite lethal changes in the type of malignant disease under consideration. No difference must be made between irradiation used as a pre operative or prophylactic treatment and as a direct therapeutic agent It must therefore be given as intensively as was humanly possible—between 3000 and 6000 r in three to six weeks Irradiation would only be of value in that type of case in which it had some curative value when used alone A lesion which was genuinely inoperable when first seen could not be rendered operable by irradiation unless it was at the same time fully cured and required no operation. An already operable lesion might be rendered more operable by clearing up sepsis and lessening growth by shrinkage Such a growth might appear operable but still be massively infiltrated; the surgeon who found that he could not remove it could not be rescued from the consequences of his misjudgment by his radiological colleague and the patient was worse off than he would have been if he had been treated as an inoperable case The general outlook must be that of radical excision and radical irradiation as two distinct methods Each method must be so thoroughly employed that it achieved in its own right a definite percentage of cures without leaning on the other The combined method achieved a summation of results rather than of effects

Miss Louisa Martindale cited her own figures of 246 cases of cancer of the breast to show the value of post-operative irradiation with X rays The ten year survival rate was higher among the patients who had had glandular involvement than among those who had not these were the cases in which she had used adequate X ray therapy The earlier cases in which she had used apparatus which she would now consider inadequate had seemed to give just as good results perhaps because she had continued the treatment longer than if she had been using a higher voltage Later she had found that 156 kv gave a more successful hardness of rays than higher voltages Adequate X ray therapy should always be given after every radical amputation Dr Martindale supported this assertion by consideration of the statistics of foreign clinics She had used pre operative treatment in some cases but only where the patient had been kept waiting for a bed. She quoted a case of an atrophic scirrhus in the right breast which had received intense and prolonged pre-operative treatment from Prof Coutard and afterwards undergone a small mastectomy to show how resistant this condition might be The tissues had seemed to have a subcutaneous œdema and the skin no elasticity living cells were found in many different areas It seemed therefore worth performing the radical amputation first wherever possible and following it by steady X ray treatment

Dr Douglas Webster quoted Bloodgood's opinion in favour of pre-operative irradiation saying that this treatment doubled the value of surgery The value of pre-operative irradiation was most clearly shown in borderline or inoperable cases If it could do so much in advanced cases it could probably do still more in milder and operable cases It could add about one-third to the value of post-operative irradiation and was perhaps particularly useful in malignant kidney

Dr M C Batten doubted whether deep X ray therapy would irradiate the far side of a large mass as thoroughly as the near side Rays from the million volt tube might do it, though they would probably pass clean through the tissues instead He advocated removal by efficient surgery followed by radium or X rays

Dr J E A Lynham declared that pre-operative irradiation could have no immunising effect on any growth which was not given direct irradiation He did not agree with Dr Paterson's surgical conception of post operative irradiation—a massive dose in a short period A certain number of cells often survived even in the periphery of the mass, where the intensity of the irradiation should have been greatest A sublethal dose continued over a period might cause some of the cells to die out but the patient's tissues had to be considered as well as the growth Excellent figures had been obtained in the days before high voltage therapy

Dr B W Williams quoted Bloodgood's figures for post operative irradiation In two series one of which received no irradiation and the other post-operative irradiation restricted to prophylactic treatment of the breast area and supraclavicular glands where no secondaries were apparent the total mortality at the end of three years was identical and the total recurrences in the irradiated series were slightly greater than in the controls

SECTION OF ORTHOPÆDICS

At a meeting of this section held on March 2nd with Mr B Whitchurch Howell, the president in the chair a discussion on the prevention and treatment of

Ununited Fractures

was opened by Mr A M A Moore He said that the problem of the ununited fracture was as serious to day as it had ever been in the past He had gone into the records of 60 cases of non union that had been treated at three London hospitals in the last ten years, the difficulty had been to obtain accurate records of their early management as 45 of them had been treated at some other hospital and had only presented themselves for final treatment with the non union established They had all been in patients, the fractures were of six or more months' duration, and fractures of the neck of the femur had been excluded from the series, since that problem could be regarded as solved In the first half of the ten years there had been 29 cases and in the second 36 In spite of the improved methods ununited fractures thus seemed to be more frequent The Wassermann reaction was positive in 2 of the 39 patients in whom it was performed, the fractures in these were of the clavicle and tibia No general factors could be established for the causation of non union One patient had been radiographed 45 times in 5 weeks, but as the fracture had also clearly been over extended by skeletal traction, this could not be blamed for the non union Radiological evidence of bone infection was found in 19 cases, 14 being in the first half and 5 in the second, 11 had originally been compound fractures and 8 simple Operations such as plating had been primarily responsible for non union in 13 out of these 19 cases, the smaller number of infected cases in recent years might be because fewer were now being plated There were also 20 cases shown by radiography to have been over extended for a prolonged period during the primary treatment, many others appeared to have been but proof was lacking The speaker's impression was that while skeletal traction was an extremely valuable method of extension it had been used without due care in many cases recently A short period of over extension was probably of great value in reducing deformity, but the weight employed should be considerably decreased as soon as possible He thought that the 5 cases of fractured phalanges had not been satisfactorily immobilised.

Mr R Broomhead said that the diagnosis of non union was based on movement and pain at the site of fracture when stress was thrown on it, and on sclerosis of the ends of the bone as shown in the radiogram He discussed the treatment of some kinds of ununited fractures by reconstruction and bone grafting, where shortening was immaterial the ends of the bone could be reshaped and fixed without a graft, but where maintenance of length was essential or removal of sclerosed bone had left a gap grafting was called for His choice of method of grafting was to use bone chips for spinal grafts, but in ununited fractures of long bones the periosteum, which was essential for success in that operation, was apt to be turned into fibrous tissue He thought that as large a piece of bone should be used for the graft as was compatible with the mechanical conditions present and that it should be firmly fixed When there was a gap he performed a sliding inlay graft and filled up the gap with chips, there was, however, the danger that the graft would snap When non union was persistent and associated with pain amputation might be advisable Operation on the humerus was made difficult by the musculospiral nerve, bone grafting of the femur was one of the biggest surgical procedures All his cases were fixed in plaster for three months and then given remedial treatment

Mr H A T Fairbank thought delay in union was as common now as it had been twenty years ago He thought the common causes of delay were local, not general, and that, in addition to imperfect immobility, faulty apposition and poor blood supply were causes He had seen the custom of splinting give place to mobility and massage, the two methods seemed to give equally bad results Many modern cases of delayed union were due to too early massage and movement, others to open operation without adequate screws or proper immobilisation Malposition was very important, he had been impressed by finding no suspicion of an attempt at union when operating on cases six months after fracture, and yet when put in apposition and plated for immobility the ends had united without delay He agreed with Mr Moore that over extension was a real risk and felt that students should not leave hospital with the idea that skeletal traction was the routine method of treatment although it was the best for fractures of the lower end of the tibia and fibula Callus formation and the amount of ischæmia might be important but the position was the deciding factor in choosing a course of action He preferred to operate before delayed union had passed into non union, grafting was commonly the best treatment, although an intermedullary peg was very useful for the humerus and femur He too feared the graft would snap Living autogenous grafts had advantages over all others It was a mistake to try to correct completely the deformity of fractured ulnar and radius Circular bands of wire were undesirable because of the risk of making weak spots in the bone

Mr G R Girdlestone said he believed the principal factor turning delay into non union was impatience A patient of his had had part of the upper end of the tibia excised and a piece of fibula put in the gap together with chips He did not know whether the fibula or the chips had been responsible, but he could believe in both so long as the case had adequate after-care Many cases would unite if the ends were freshened and brought together He had believed that grafting provided a certain number of cells and some scaffolding, but in one difficult case in particular it had failed. He had come to accept as a rule for cases of non union one that applied to amputation stumps—one should not be fussy repeated operations were to be avoided The patient should be put up in an ambulatory splint and told to go away for 6 to 9 months Bone developed some lack of response if repeatedly traumatised, and in that way differed from carpenters' material. The three essentials were immobility without circumferential pressure, intermittent end to end compression, and a good blood supply The failures, apart from sepsis, came from poor blood supply, and that was where drilling and opening up of sclerosed tissue played an important part He made a point of never raising the ends of the bones from their beds, for that meant that only one side could be approached at a time and two operations were sometimes necessary instead of one He had dealt with 9 cases of non union in the last five or six years and had had one failure

Mr K H Pridie pointed out that in the radiograms of femurs shown the fracture had in several instances been transverse, there was an inverse ratio between area of fracture section and the time taken in consolidation, but most people confused the terms united and consolidated He had only had one failure in union in 4000 cases Long bones, if healthy, readily united after fracture, and non union was due to treatment, the commonest cause was over traction, and after that inadequate immobilisation, which had stopped before there was consolidation, or when a plate kept the bone ends apart After comminuted fracture of the tibia with loss of bone, the fibula might unite early and separate the two ends of the tibia the fibula should then be divided to allow the fragments to come into apposition. To prevent non union fractures should not be left to house surgeons to treat traction should only be used to reduce the fracture once achieved the traction should be stopped and immobilisation be obtained by plaster for knee and arm fractures by fixed traction for thighs Skeletal traction should only be used for compound fractures it was difficult to overpull with strapping extension Compound fractures should be treated efficiently converting them into simple closed ones Fractures should be immobilised with function until there was consolidation Treatment of non union consisted of removing plates and foreign bodies If the bones had become sclerosed and indolent multiple drilling would reactivate the ends; this could be performed through a tenotomy incision Where there was a large gap the fracture should be exposed and a rotary saw used up and down the fracture site as well as drilling

Mr D McCrae Aitken thought the causes of non union were movement compression and lack of apposition —Mr E I Lloyd said that the patient should be walking as soon as possible He considered that union was liable to take longer than the three months mentioned by some authorities —Mr B H Burns had not had a happy experience of wire radiograms had shown definite absorption near it He was startled by Mr Fairbank s suggestion of steel plates when union had occurred in his cases it had done so at the point furthest away from the plate

Mr N St J G D Buxton had seen 24 cases of non union of the tibia in 8 years two were congenital fractures neither had united and one had been amputated; two in middle aged women had joined and 20 had had osteotomy performed on the fibula, both broken ends of the tibia being freed and cleaned and a bone graft was brought down. This, he considered, was the operation of choice; it allowed angulation to be corrected at the same time.

Dr J Duncan White thought complete immobility was essential for obtaining union. Even the 45 radiograms taken in five weeks mentioned by Mr Moore was not likely to be an overdose for the patient

The President said that he had found non union to be due in several cases to interposition of fibrous tissue Massive wide bone grafts with stripping up of the periosteum and freeing of the ends of the bone gave he thought the best results He had recently been using a deeper and wider saw The messier the operation the sooner union was obtained and the better the result He believed that metal had to be used sometimes for instance to save a limb with a compound fracture

Mr Broomhead in conclusion said that he used rustless steel wire but where a plate was also used the wire and plate should be of the same metal He agreed that skeletal traction was used too much He had noticed that particularly tall people and those with multiple fractures were more liable to non union he wondered whether there were some substance which influenced bony union and which expended itself in tallness and many fractures. Mention had been made of the increase of ununited fractures recently but of course there had also been more fractures altogether

MEDICAL SOCIETY OF LONDON

At a meeting of this society held on March 8th under the chairmanship of Mr W E Tanner a discussion on

Effects of Prolonged Dorsal Decubitus

was introduced by Mr G R Girdlestone. He said that, apart from renal stone the effects of prolonged dorsal decubitus were too indefinite to reach any index system of hospital record. He had had to rely on the investigation of a small group of cases on his clinical experience, and on the response to a questionnaire of a number of colleagues The effect on general health differed as between children and adults and in closed wards as opposed to open air wards where part of the body was exposed to the sun or to sky and wind for suitable periods every day The child in an open air ward in an orthopædic hospital was in better health than a middle class child in school or home. Adults did not tolerate prolonged dorsal decubitus well, and were less benefited than children by heliotherapy Adults usually stagnated after a time, especially if they were splinted The freer the body from control the more could the patient respond to the stimulus of the open air Opinions differed as to whether the shape of the thorax was altered by the decubitus two doctors mentioned some antero posterior flattening which should be countered by exercises and by the adoption of the ventral position Twenty cases taken at random all discharged for more than a year after periods of from one to eight years in a position of decubitus showed no abnormality in chest shape On vital capacity he had not been able to get more information than a general impression that it was not altered by prolonged decubitus Deformities in lower limbs was very much a matter of control partly by splintage and partly by nursing care Inadequate nursing might lead to clawing of the toes, genu recurvatum genu valgum and so forth and possibly fixation of a joint in a deformed position Pyæmic arthritis of the hip might progress to pathological dislocation in an insidious way In his orthopædic hospital the feet and ankles were as far as possible left free in cases of spinal and hip disease and they were given frequent periodical exercises controlled by the nursing staff Of 20 hospital patients recently examined who had been in dorsal decubitus more than a year 10 had slight pes cavus of 20 who had been out of the hospital for some time only 1 had cavus deformity and that only slight A few patients developed subastragaloid valgus of the foot the tendency of which was to cause flat foot but that was prevented by weighting the heel when the patient got up Splints devised to prevent deformity could, if misapplied cause deformity Lordosis could be brought about by unrecognised flexion deformity of the hip and it was almost impossible to correct this by passive movements Usually scoliosis had an organic cause; that resulting from infantile paralysis came on rapidly, and the deformity might catch one unawares

In open air wards the blood picture tended to become normal and in many cases that meant improvement Decubitus seemed to have no detrimental effect on the blood but patients lying on their backs for a long time seemed more sensitive than others to shock after a prolonged operation Mr Girdlestone s observations lent no credence to the idea that prolonged decubitus lowered the blood pressure Neither he nor his colleagues had noticed any abnormality in kidney function as a result of posture alone; but dorsal decubitus predisposed to renal calculi. Here there were two factors at work: posture and infection. When stagnation coincided with concentration of the urine, precipitation was likely to occur. Care about the intake of fluids and dehydration was needed, and a frame should be used for rotating the patient many times a day to aid the flow of urine from the pelvis of the kidney, in the gravitational direction. In 180 beds in his hospital perhaps 100 patients were in a position of dorsal decubitus; and in the last 10 years there had been only 8 cases of stone. In the last 5 years, during which specific measures of prevention had been operative, only 1 patient had developed stone. Early diagnosis of renal stone was very important, as treatment by copious fluids and frequent rotation seemed often to cause its disappearance. Renal stone had been attributed to a diet with deficient vitamin A and excess of vitamin D.

Bed sores were now very rare in orthopædic hospitals since the nursing staff understood the use of the frame, the plaster bed, and so forth. In the last few years only one case of persistent bed sores had occurred in his hospital, in a schoolboy with paraplegia following a spinal fracture. Lastly, Mr Girdlestone spoke of the effect on the mind of prolonged dorsal decubitus; this could be partly averted by cheerful lighting, the provision of games, and the promotion of good cheer.

DISCUSSION

Mr **JENNER VERRALL** said that the orthopædic surgeon tended to concentrate on the particular deformity, and might not notice the other features.

Mr **JOHN EVERIDGE** said that, as consulting urologist to the Carshalton Orthopædic Hospital, he had observed many cases of renal calculi associated with dorsal decubitus. In the war attacks of hæmaturia had occurred with stone formation in many patients after prolonged recumbency due to injury. In most of them urinary sepsis was present, and the most common organism was *B. coli*, though there were cases of *B. proteus* and streptococci; staphylococci were not as common as was expected. Hæmaturia with or without urinary sepsis was prone to occur in children who were kept on their backs; in girls it was difficult to avoid contamination following defæcation, the infection being an ascending one by way of the urethra. Stagnation caused by gravity must be a factor in the causation. In cases treated in the Trendelenburg position there was a tendency for stones to form in the high calyx; those children were never thirsty and it was difficult to get them to drink enough. They tended to become constipated, and the aperients given were sometimes too drastic, for violent action of the bowels promoted coli infection of the urinary tract. Disordered calcium metabolism was probably a factor, but in these children it was difficult to demonstrate hypercalcæmia.

Since heliotherapy led to perspiration and the loss of body fluid, these children were kept in the shade as much as possible. Many of the stones were painless, since they caused no obstruction. The prognosis was serious, but not so bad as might be thought. Often calculi, huge judging by the radiographic shadows, disappeared; these shadows were presumably not due to formed calculi, but to the silting up of what was called 'mud,' which disappeared when the patient resumed normal life. Formed stones also had been observed to disappear to some extent. These children were liable to sharp attacks of ureteric colic with great dilatation of the ureter due to secondary impaction of a stone. The methods at the Carshalton hospital had definitely lowered the incidence of stone. Most of the stones were mixed: ammonium, urate, phosphate, magnesium.

Mr **G. B. WOODD WALKER** thought it unlikely that gravity could make much difference to the emptying of the pelvis of the kidney. Recently a film was exhibited at the Royal Society of Medicine showing great activity of the pelvis of the kidney and the ureter. Man and animals could swallow "uphill," and he did not see why urine should not be passed, whatever the position or posture of the kidney. There was little evidence to support the idea that the upright position in man made any difference to the draining of the kidney. He agreed that there must be great stagnation in these patients, and decalcification must be an important feature.

Dr **G. E. VILVANDRÉ** remarked that in osteitis fibrosa there occurred a vast decalcification. He had seen the formation of calculi in cases of Paget's disease which were sent for an X ray examination because of urinary symptoms. In some of these he had seen not only calculi in the bladder but also evidences of Paget's disease. Decalcification could result from mere disuse. He had been interested to hear that calculi could disappear more or less spontaneously. Some elderly patients might give the impression, judging by the radiogram, that they had Paget's disease, but further investigation showed this was not so, as there was no bone softening, nor enlargement at the epiphyses; it was simply decalcification due to old age.

Mr **B. WHITCHURCH HOWELL** said he had a shock in 1920 when a young patient with double dislocation of the hip joint had developed hæmaturia a few weeks after commencing a course of reduction by treatment on her back. She developed renal calculi in both kidneys. He worked out, for the patient, a pelvic rest arrangement which kept her in the required position on a hinged support, which enabled gravity to act and the urine to be secreted downwards. Since he had been using that apparatus he had had no further cases of renal calculi and hæmaturia. In the old days patients were kept on their back so long that cardiac efficiency diminished, and probably blood pressure was reduced. Patients kept in an apparatus with a flexion of 30° had no cardiac inefficiency but increased respiratory movement, and they could pass urine naturally and in larger quantity. Many cases were now treated with the Bradford frame. This he had incorporated into a four-poster bed, and by its means a case of spinal caries could be turned through a quarter circle, so enabling the sun to play on the back or on the chest at will. These patients should have definite limb exercises supervised by the nurse, and much fluid to combat constipation. While making the X ray examination of the hip condition it was not unusual to find hard fæces in the pelvic picture. Psychologically, these patients had much to contend with. Recently their lot had been much improved by providing them with prismatic spectacles. An arrangement of mirrors would enable them to appreciate cinema pictures without getting into strained positions. The colour scheme of these wards should be made more restful with more mauve and subdued colouring. Very few of the occupants of orthopædic beds were supplied with proper tinted glasses.

Mr **A. SIMPSON SMITH** said he had treated a girl, aged 18 months, on a Hughes frame at an angle of 75°, and she developed severe bilateral pyelitis and otitis media which he and his colleagues attributed to her posture He agreed with what had been said about decalcification but he felt that gravity had as much influence in these cases. It seemed impossible that, against gravity a kidney by its contractions, could force urine 15 in into the bladder and keep it there Even in the decubitus position the kidney was lower than the bladder and the urine would leak back unless there was a very tight fit.

Mr F M. LOUGHNANE did not think the decubitus posture had much to do with the formation of stones. For a long time he was at the Hospital for Sea-Bathing at Margate, and he did not remember one patient there developing urinary symptoms or stone in the kidney unless in association with renal tuberculosis. As to the dehydration accompanying exposure to sunlight causing stones he was in Mesopotamia four years but saw only two patients with urinary calculus If a kidney could not secrete urine because the patient was on his back, and stagnation occurred, there should be hydronephrosis, and none of the pictures exhibited showed hydronephrosis When once formed, he did not think a renal calculus would disappear unless passed naturally

The CHAIRMAN said that in all cases of long standing infection it was possible for the pelvis of the kidney to be full of urates, which did not show on the radiogram He had a patient who in consequence of extensive suppuration of the type seen in the war had to suffer amputation of the leg just below the hip His night urine did not exceed 8 oz and the day urine 12 oz probably the kidneys had large uratic deposits in the calyces.

WEST LONDON MEDICO CHIRURGICAL SOCIETY

A MEETING of this society was held at the West London Hospital on March 5th under the chairmanship of Mr NEIL SINCLAIR when a discussion took place on

Diseases of the Colon

Dr A. F HURST discussed the symptoms in organic disease of the colon especially discomfort and pain for which the characteristic situation was the left iliac fossa. Any change of the normal bowel habit should be noted as suggestive of disease of the intestines and more commonly of the colon It was important to make a rectal examination and to examine the stools In Dr Hurst's view there was no such thing as mucous colitis The mere presence of mucus was not evidence of colitis it was normally secreted in persons taking aperients all of which acted as chemical irritants of the bowel. Mucus only indicated inflammation if it was present in a loose stool which was naturally produced that is, not the result of an aperient Colitis Dr Hurst continued began exactly like an ordinary dysentery In this connexion he pleaded for the use of the proctoscope by general practitioners With regard to carcinoma of the rectum and colon he believed that nearly all cases originated in polypi. Carcinoma of the colon might produce general ill health with no local symptoms, and this should be borne in mind when any person over 35 complained of general unfitness and nothing abnormal was found on general examination Occult blood should be looked for in suspicious cases. Pain in the left iliac fossa was often due to diverticulitis most sufferers from this condition could be treated medically and it was amazing how a diverticulitis might respond to medical treatment. The medical treatment was rest in bed, a non-residue diet, no aperient, and increasing doses of belladonna 6 oz of liquid paraffin might be given as an enema at night

Prof G GREY TURNER, speaking from the surgical side, said that occasionally the inflammatory condition did not remain limited to the bowel but caused localised peritonitis and a tendency to the development of internal fistulæ Surgeons were apt in a case of fistula between colon and bladder to attempt too much at a time If anything had been learned during the last ten or fifteen years it was the extreme importance of dealing with these things in stages For a communication between the large bowel and the bladder a preliminary colotomy should be the first step any larger measure only at a second intervention Diverticuli did not appear to be in any ancestral relationship to malignant disease though the two conditions occurred in the same types of individuals and at about the same period in life

Dr H W POST showed a large number of radiograms and discussed the two principal means of examining a patient—namely (1) a barium meal to estimate the physiological condition of the large bowel and (2) a barium enema, which showed the anatomical appearance and any pathological changes. Carcinoma of the rectum was rarely diagnosed by means of X ray examination.

Mr CECIL WAKELEY said that most carcinomas of the cæcum were not diagnosed until the tumour was very large They did not give rise to obstruction until an enormous growth overlapped the ileocæcal valve. A surgeon was apt on exposing such a tumour to consider it inoperable and to do a palliative ileocolostomy But later it would be found that it was no longer fixed, the fixation being due not to the growth but to the superadded sepsis When after colostomy the irritation disappeared, the growth became more mobile One of the most important things which had crystallised in surgeons minds was that in carcinoma of the colon multiple operations had to be done.

Dr MAURICE SHAW spoke of the condition known as spastic or hypotonic colon and its treatment by large doses of belladonna The other principle in treatment depended on recognition of its possible psychogenic origin; treatment must be largely a question of routine He had watched the treatment of colitis for some 15 years, and to his mind no very significant advance had been made apart from dietetic treatment It was most important to encourage the patients to take as full a diet as they could He felt there was some possibility of doing good by protein shock though he had found no benefit from serum therapy

Mr C F G BATCHELOR spoke on the desirability of performing colectomy in the presence of secondary growths in the liver In one case in which such growths were manifest he had done a colectomy and for two years the patient was quite comfortable When the patient returned secondary growths were found in the pouch of Douglas and the liver was not enlarged at all.

Dr GEOFFREY KONSTAM said that he was always hesitant about diagnosing spastic colon and nowadays with the accessory methods available some sort of confirmation was desirable. With regard to the use of belladonna if this treatment were pushed to the extent which Dr Shaw had suggested it would mean that the patient would not be able to read because of the paralysis of his accommodation would not be able to speak because of the dryness of his mouth, and would not be able to eat because of the drying up of the secretions of his stomach.

EDINBURGH OBSTETRICAL SOCIETY

AT a meeting of this society held on Jan 13th, with Dr DOUGLAS MILLER, the president, in the chair, a paper on the

Treatment of Placenta Prævia

was communicated by Prof JAMES HENDRY (Glasgow) and Prof. DUGALD BAIRD (Aberdeen) They began by reviewing the opinions expressed at a meeting of the society in 1925, when the same subject was discussed Cæsarean section was then thought suitable for a few hospital cases, but vaginal methods of controlling hæmorrhage and effecting delivery were given first place and no reference was made to the importance of making up the patients' blood loss From consideration of large series of cases there appeared to be a uniform international standard of maternal mortality for placenta prævia in the neighbourhood of 7 per cent , but limited series had been reported showing a much lower mortality, and the speakers felt that much better results could be obtained Ninety cases had proved fatal in the Glasgow Royal Maternity Hospital in the period 1925–34, death being due to hæmorrhage in 54 cases and sepsis in 36 Two groups were recognised (*a*) those reaching hospital in good condition, and (*b*) those arriving in poor condition The mortality was higher in the latter, it also increased with the degree of placenta prævia The following recommendations suggested themselves

(1) If possible, every case of placenta prævia should be dealt with in a maternity hospital or well-equipped nursing home, but if the patient is already collapsed a blood transfusion should be given in her own home before *she is removed, and for this purpose* a mobile blood transfusion unit should be organised

(2) The importance of warning hæmorrhages should be more fully appreciated

(3) Cases of antepartum hæmorrhage should not be examined vaginally except in circumstances that allow of efficient treatment being carried out at once, and then only by a person qualified to carry out such treatment

(4) The blood loss must be replaced by blood transfusion

(5) Cæsarean section should be considered far more frequently, for it offers a very satisfactory form of treatment

(6) The successful treatment of the placenta prævia requires *the coöperation of the general practitioner* and the hospital staff

If due attention were paid to these points a relatively small number of cases need be classified as "unavoidable deaths" During the last six years 228 cases of placenta prævia had been treated in Prof Hendry's unit with a maternal mortality of 2 7 per cent Where the placenta did not reach the internal os, and the patient was admitted in good condition, puncture of the membranes was carried out Occasionally in such a case, if bleeding had ceased and the child was very premature, expectant methods were adopted Where the prævia was central, or the placenta partially covered or reached down to the edge of the internal os, Cæsarean section was performed *in almost every case*, expectant treatment was never considered. The proportion of cases treated by Cæsarean section had risen to 64 per cent during 1936, the more frequent use of this *operation* had been made possible by blood transfusion, so that women arriving in poor condition could be safely operated on An efficient blood transfusion service had been established, most of the 200 donors living near the hospital Vaginal packing had been discontinued, except in grave emergencies Practitioners were encouraged to send all cases of antepartum hæmorrhage into hospital for diagnosis without themselves making a vaginal examination If the patient's condition was unsatisfactory a blood transfusion was given before any vaginal examination was made Version was used in only 8 cases in which the vagina had been packed before admission A consecutive series of 87 cases of placenta prævia had been dealt with on the lines described during the last *two* years with *only* 1 *death* (a mortality of 1 1 per cent), this death was due to the giving of incompatible blood The fœtal mortality rate in this series was 43 per cent , where *version* was *used it* was 81 per cent , where the membranes were ruptured it was 32 per cent , and after Cæsarean section it was 30 2 per cent

A group of 100 women who had had Cæsarean section performed for placenta prævia more than *two years previously* were re-examined so as to estimate the end results In 90 no abnormality was found and the general health was good In only 3 symptoms referable to the operation, probably due to adhesions, were present Of the 100 patients 54 had been sterilised, for many of them were over forty years of age and considered they had large enough families Among those not sterilised it was calculated there was a sterility rate of 8 7 per cent A group of women who had been treated by vaginal methods *in the same years as those who had* Cæsarean section was also examined as to end results Of these, 15 per cent were found to be in poor health, and the sterility rate was calculated at 18 per cent , so the *end results of Cæsarean section compared* very favourably with those of the vaginal methods The risk of subsequent sterility and of rupture of the uterus during pregnancy or labour was much *exaggerated*

HÆMOPOIESIS AND THE PITUITARY GLAND —Prof I Snapper of Amsterdam reports a series of five cases in which there appeared to be a direct connexion between disease of the pituitary gland and the functions of the stomach and bone marrow (*Ned Tijdschr Geneesk* 1937, 81, 265) In all the patients there were signs of a destructive lesion of the anterior part of the pituitary, associated with hypofunction, in one the X ray picture showed expansion of the sella turcica Examination of the gastric function revealed complete absence of hydrochloric acid in all the cases One patient, a man of 52, presented the typical blood picture of pernicious anæmia, to which, after five years, clinical signs of postero lateral sclerosis of the cord were added A second patient, a woman, had a hyperchromic blood picture (colour-index 1 27) without other abnormalities and without clinical signs of disease of the spinal cord In the *remaining three patients the blood picture* was normal, but examination elicited clear signs of combined sclerosis of the cord Prof Snapper points out that the gastric achylia in these patients, with insufficiency of the anterior part of the pituitary throws a new light upon the cases, of which a few have been reported, of so-called pseudotabes acromegalica (Sternberg) The connexion between the pituitary lesion and the nervous disturbances has never been *satisfactorily explained and the gastric achylia* appears to furnish the missing link Why this should be followed in some cases by alterations in the blood picture, in others by spinal disturbances, and in others by both, is not yet explained

REVIEWS AND NOTICES OF BOOKS

Clinical Heart Disease

By SAMUEL A LEVINE, M.D F.A.C.P, Assistant Professor of Medicine, Harvard Medical School Senior Associate in Medicine Peter Bent Brigham Hospital London: W B Saunders Co Ltd 1936 Pp 445 24s

IT is not practicable either in general or consulting practice to carry out an exhaustive clinical examination on every patient Probably the most efficient clinicians are those who exercise best judgment in a selective method of examination Dr Levine has borne in mind this principle in his clinical approach to the cardiac problems discussed in this book. He has stressed the importance of bedside methods rather than laborious special investigations in differential diagnosis The author's style is personal direct, and unusually readable Not only has he given full consideration to well known problems in cardiology, but he has also indicated in what direction further researches need to be planned and what are the mysteries still awaiting solution. Two interesting points are discussed regarding valvular disease: (1) the frequent association of high blood pressure with mitral stenosis in middle life, and (2) the common coexistence of angina with aortic stenosis; it may be that in each case the individual possesses a vascular vulnerability that exposes him to the risks of inflammatory as well as degenerative forms of cardiovascular disease. Dr Levine makes concise comments on certain recent advances in cardiological practice notably the indications for the Delorme operation in constrictive pericarditis, the treatment of chronic cardiac invalidism by thyroid ablation and the clinical features of pulmonary infarction The fever and leucocytosis in the last-named condition and the frequent absence of hæmoptysis and electrocardiographic changes are noted and the difficulty that may arise in differential diagnosis from cardiac infarction. The diagnosis and treatment of other acute cardiovascular emergencies also receive attention and among innumerable matters of practical importance mentioned are bronchial factors in cardiac dyspnœa the danger of the use of dyes for cholecystography in anginal patients and the clinical significance of systolic murmurs Dr Levine's work is not illustrated except in the terminal section on electrocardiography but it is well printed and produced.

1 Atlas of Radiographs

Third edition. By A P BERTWISTLE, M B F R C S Edin. London Henry Kimpton 1936 Pp 560 42s

2 Roentgen Interpretation

Fifth edition By GEORGE W HOLMES M.D Roentgenologist to the Massachusetts General Hospital and Clinical Professor of Roentgenology, Harvard Medical School; and HOWARD L RUGGLES M.D Roentgenologist to the University of California Hospital and Clinical Professor of Roentgenology University of California Medical School. Same publishers 1936 Pp 356 22s 6d

1 THIS book, which has now reached its third edition has been compiled, as the author points out by a clinician for clinicians and the material selected is naturally not the same as it would be in a work primarily intended for radiologists Common conditions are presented rather than rarities Great stress is laid on silhouette radiograms; probably too much importance is placed on their value. The plan of showing reproductions with a description of the condition on the opposite page is appropriate to a book of this kind for this method makes it easy for the student or practitioner to follow the different types of lesions described

Many of the radiograms are of rather poor quality and could with advantage have been replaced by more recent pictures Unfortunately from the student's point of view the radiograms are presented indiscriminately, with the left side on the left or on the right The diagnoses in certain cases would seem open to doubt. For example Fig 375 is described as an example of Albers Schonberg's (incorrectly spelled Scholenburg's) disease. In this condition the bone is dense The photograph is more suggestive of normal bone taken at too low a voltage In Fig 418 an ulcer is described as bearing radiating processes without further information one would be inclined to interpret this as the duodenal jejunal flexure In the chest section in Fig 628 it is said that the bronchial tree is very beautifully seen The radiating lines seen in the lung fields are now generally regarded as being due to blood vessels and not bronchi.

It is unfortunate that errors have been allowed to creep in to what is otherwise a useful book. In future editions the quality of the reproductions should be improved, and many of the diagnoses should be re examined.

2 Diagnostic radiology has become such an enormous subject that the authors in deciding to survey the whole field have found it impossible to give more than very brief consideration to abnormalities The statements made are however reliable and the subject matter is clearly set out In this edition several sections have been rewritten and many fresh radiograms have been added. The greater part is devoted to the commoner bone and joint diseases only brief mention being made of the rarer conditions In the section on heart and great vessels new methods of measurements are given; the section on lungs and the gastro-intestinal tract has been brought well up to date Pyelograms have been more widely used to demonstrate lesions of the renal tract. This whole subject has been compressed into twenty pages The quality of the reproductions is good and the examples chosen are typical. The book should not be regarded as a complete text-book, but it will serve as a useful and reliable introduction to radiology

Dental Surgery and Pathology

Third edition By T W WIDDOWSON L D S Dental Surgeon to King's College Hospital; and E W B WIDDOWSON L D S London: John Bale Sons and Danielsson Ltd 1937 Pp 724 35s

THIS book began in 1914 as a notebook for students and now it has expanded into a large work of over 700 pages It still retains the essential character of a notebook in being a compilation of knowledge from other sources set out as far as possible in tabular form. But a notebook of this bulk seems to miss the mark It is too big to be a guide or spur to the memory and yet lacks the organic unity of a formal treatise The student reading this book may collect facts but he will scarcely gain a coherent impression of his subject. As a work of reference however this book has a valued place especially in the libraries of those with sufficient knowledge to winnow out important information from that which is trivial or obsolete A special word of praise is due to the chapter on the treatment of irregularities of the teeth by Mr Russell Marsh, which provides an excellent *résumé* of the subject

Chronic Diseases of the Respiratory Tract

Diagnosis and Treatment By ELMER H FUNK, M.D, late Clinical Professor of Medicine and Therapeutics, Jefferson Medical College Revised by BURGESS GORDON, M D, of the Jefferson Hospital, Philadelphia London Humphrey Milford, Oxford University Press 1937 Pp 618 40*s*

THE revision of Elmer Funk's book was entrusted after his death to Dr Gordon, who has brought it up to date by the inclusion of recent work on thoracic surgery, pulmonary asbestosis, and so forth In general the book conforms to the usual pattern both as regards subject matter and arrangement, illustrations, mainly skiagrams, are numerous and well chosen Therapeutics receive more attention than is customary, the classified description of expectorant drugs and the mode of action of each being particularly useful In view of this it is surprising to find no more than a passing reference to postural drainage in the treatment of pulmonary abscess The authors insist clearly on the need for establishing adequate drainage in this condition and advocate bronchoscopic treatment in the acute stage followed, if necessary, by surgical intervention before the walls of the abscess cavity have become rigid

In the treatment of pulmonary tuberculosis due emphasis is placed on the need to continue bed rest for some time after the cessation of symptoms of activity In describing the maintenance of artificial pneumothorax the writers pay less attention to radiological control than we do in this country, they consider that "the safest range for intrapleural pressure is from minus 2 to plus 2" and do not appear to be concerned with the marked mediastinal displacement which occurs in certain cases even at these relatively low pressures

A Preface to Nervous Disease

By STANLEY COBB, A B, M.D, Bullard Professor of Neuropathology, Harvard Medical School, Psychiatrist in Chief, Massachusetts General Hospital London Baillière, Tindall and Cox 1936 Pp 173 13*s* 6*d*

Prof Cobb describes his book as "a preface, to start the student with a three dimensional orientation towards neurology and psychiatry—a brief, concurrent anatomy, physiology, and pathology" The early chapters deal with the anatomy and physiology of the autonomic nervous system, the pathways of sensation and the integration of movement and locomotion Then follow chapters on functional localisation in the cerebral cortex and consciousness and the "mind-body" problem After dealing with the anatomy and physiology of the cerebral circulation and the cerebro-spinal fluid Prof Cobb discusses the general and special histology of the nervous system, and the book ends with a consideration of epilepsy and the psychoses

The author's long experience as a teacher has enabled him to realise the difficulties of students encountering the complex subject of neurology for the first time, and he has succeeded in packing a surprisingly large volume of useful information into a short book Like the nervous system itself the book is well integrated Structure is explained in terms of function, and abnormal physical signs are interpreted as the expression of disordered physiology The exposition is clear and aided by useful simple diagrams and tables, and the list of references with which each chapter concludes will be of value to those who wish to know more of the subject In a few details the views expressed are not those generally accepted Few pathologists will agree that arterio sclerosis is a cause of intracranial aneurysm, or that paralysis agitans is one of the commonest results of focal arterio sclerosis The view that symptomatic herpes is due to a physiological disturbance and not to the herpes virus is nowadays against the weight of the evidence, as is also the statement that epilepsy is rarely inherited as a syndrome without the inheritance of other associated neurological disorders The attempt to include an introduction to psychiatry has not been altogether successful, for this is too large a subject to be adequately discussed as an addendum to an introduction to neurology Moreover, in dealing with psychological questions such as the "mind body" problem Prof Cobb betrays a bias not uncommon in pathologists, tending to regard a functional disorder as the manifestation of a minute but as yet unknown structural change But it is only certain details of this kind that are open to criticism In essentials the author has achieved his purpose, and his book should make a wide appeal to students

Introduction à la chirurgie genito-urinaire

BY Prof E E LAUWERS, Ghent University Paris Masson et Cie 1936 Pp 197 Frs 32

Dr Lauwers has already published introductory works, similarly planned on the surgery of the nerves, thoracic surgery, and plastic surgery No better description of the aim of this new volume can be given than that written by Prof Legueu in the preface "It is neither a treatise nor a manual for he deals with neither instrumentation nor technique. It is rather a general view of his subject, a bird's eye view of the pathology of the urinary system, and of the general principles that must be kept in mind in dealing with departures from health" Pascal, in writing to a friend, once remarked that his letter was too long, he had not had the time to shorten it Dr Lauwers has given himself the necessary time. He has included in his bird's eye view not only the whole of genito urinary surgery, but also conditions that are usually included under other specialties The book closes with a description of disturbances of menstruation and of sterility The chief question that rises to our mind after reading it is for whom is it intended? The title suggests that it is meant for the beginner, but the absence of those details on which examiners set such store will be a serious defect in the eyes of the medical student

Year Book of General Surgery, 1936

Edited by EVARTS A GRAHAM, A B, M D, Professor of Surgery, Washington University School of Medicine Chicago Year Book Publishers, London H K Lewis and Co, Ltd. 1936 Pp 831 12*s* 6*d*

AGAIN the author deserves congratulation upon this useful compilation The articles are well selected and extracted and cover the whole of general surgery All surgeons should have this book which makes reference easy and anyhow serves to recall to mind important contributions made during last year Few active practitioners will not find here accounts of progress which had previously escaped their notice Altogether an excellent annual.

THE LANCET

LONDON SATURDAY MARCH 13 1937

THE NEED OF A MEDICO LEGAL INSTITUTE

THE project of a medico-legal institute has now been long enough before the public to breed impatience at the delay in its initiation A year ago the Departmental Committee on Coroners presided over by the Master of the Rolls and manned by an impressive proportion of legal members, alluded to the institute as if it were already visible upon the horizon Envisaging it as a training centre for medico-legal experts and a focus of pathological research the committee was prepared to accept its diplomas and degrees as a very proper qualification for appointments to an official list of pathologists available for post-mortem examinations in connexion with coroners inquests Last June the Advisory Committee on the Scientific Investigation of Crime unanimously recommended the establishment of a national medico legal institute in London and sketched its scope and functions The recent republication in the *Medico-Legal and Criminological Review* of Dr W G BARNARD s paper on the subject with the comments of Sir BERNARD SPILSBURY Sir WILLIAM WILLCOX and others offers a practical scheme and brings the proposals to a point where decision and action need no longer be delayed

Three simple questions arise at the outset How much will the project cost ? Where will the institute be placed ? And what authorities will be responsible for its management ? To cover the capital expenditure on buildings and equipment Dr BARNARD hoped for a grant from the Central Government supplemented perhaps by contributions from the London County Council and other interested bodies Once this initial cost was over he had an excellent suggestion for meeting the annual cost The London County Council pays not less than £20 000 a year in fees for post-mortem examinations ordered by metropolitan coroners and for medical evidence given in their courts The Departmental Committee on Coroners advised higher statutory fees for this purpose in view of the superior attainments for the expert pathologists whom it wished to see employed If this recommendation received effect the annual sum would be so much the larger If the total could be pooled and made available for the proposed medico-legal institute the annual expenditure could reasonably be met therefrom and the institute by providing the expert services required would quickly justify its existence and embark upon a specific programme which could be afterwards enlarged at discretion It would be training skilled pathologists for official or other purposes it would aid alike the cause of general medical education and the essential needs of those who administer justice The site for such a centre, it has been sensibly suggested, should be near the main buildings of the University of London If it were possible to locate one of the London coroners courts under the same roof there would be educational and other advantages from the association Dr BARNARD is probably right however in not wishing to see the scheme of a medico-legal institute linked too closely to a municipal system of coroners courts

The government of such an institute is an interesting and by no means insoluble problem The marriage of medicine and law usually leaves one of the pair predominant Both must have their say The Bar Council and the Law Society must be persuaded to make their contribution along with the bodies which represent surgery and medicine The Home Office will be keenly interested and although a too official atmosphere might not be healthy the invisible resources of the Privy Council might be called upon in the organisation of the scheme especially if a Royal Charter be sought The local authorities of London have their part to play It is understood that the University of London may not be unwilling to recognise the institute as a teaching school and to create in it a chair of medical jurisprudence There is a mass of detail to be worked out but the principle is both acceptable and accepted The time is ripe The omens are favourable Who will take the first step ?

ACUTE INTESTINAL OBSTRUCTION

THE fatality of high intestinal obstruction has long been a mystery for it is obviously not starvation that reduces a previously healthy person or animal to a moribund state in the course of a few days The ease of the experimental attack and the importance which would be attached to its solution have led many investigators to tackle the problem but none of their theories have really stood the test of time and criticism For a number of years toxins were thought to be the lethal factors Then with the advance of biochemical knowledge the importance of the loss of extracellular fluids and electrolytes began to be appreciated The ability of saline infusions to prolong the life of animals with obstruction supported the view that the real cause of death was extracellular dehydration For a time indeed the riddle seemed to have been answered but there were always a number of findings that were not explained by a simple loss of extracellular fluids When histamine was discovered and its pharmacological properties explored, there seemed to be a chance of satisfying the experimental and clinical demands by combining the two theories and naming histamine as the toxin , but it soon became evident that this was not to be A factor was still missing

It has been known for some years that one of the features of experimental and clinical Addison s disease is a rise in the serum potassium and the importance of this was much emphasised by the publications of 1030 Attracted by the many common features of Addison s disease and acute intestinal obstruction, a group of New York investigators[1] performed experiments on cats and are able to show that in these animals high intestinal obstruction is accompanied by a rise in the blood potassium to levels that they regard as lethal This is a definite advance in knowledge and if the experimental findings are confirmed in other animals, and particularly in man, a real step forward will have been made

One always hopes that new knowledge will lead to an immediate advance in therapeutics It must be admitted, however, that unless the administration of the suprarenal extract "cortin" will do the trick, the emergency physician or surgeon is likely to find the lowering of serum potassium almost as difficult as the removal of hypothetical toxins

AMŒBIC DYSENTERY IN CHICAGO

LIKE pilgrims to the holy city of Benares, eight and a half million people visited the "Century of Progress" exhibition in Chicago during the summer and autumn of 1933 They made epidemiological history, for at a cost of about a hundred lives they proved that amœbic dysentery could occur as an extensive water-borne epidemic in a civilian population The report on this epidemic now issued[2] is comprehensive and deserves the close attention of epidemiologists and protozoologists Briefly, the investigations of the board of health and the division of water purification of the city of Chicago and the U S Public Health Service appear to have established the following facts Two hotels, whose water supply was partly in common, were the source of the outbreak, and two major sanitary defects were found In one hotel cross connexions were discovered between a sewer and discharge pipes of condenser-water which, after being used for cooling, was distributed to the hotel and to the upper floors of the second hotel in certain conditions of overloading of the sewers and heavy rain this water might become polluted by backwash up the pipes Secondly, in the same hotel, leakage round a rotting wooden plug in an overhead sewer could contaminate a cooled drinking-water tank below

In the previous eight years 232 cases of amœbic dysentery had been reported to the Chicago board of health Of these, 8 6 per cent were subsequently traceable to the two hotels, and an investigation in 1926–27 had shown a carrier-rate of about 5 per cent in their employees Of the 1409 cases reported during the 1933 epidemic, 1050 were among guests or employees of these hotels, and during the epidemic itself the incidence of carriers among the employees rose to 37 8 and 47 4 per cent, with a corresponding risk of pollution of the water supply As was to be expected from the nature of the disease there was a long latent period—averaging over three months—between exposure to infection and notification of the illness to the Chicago health authorities The incubation period varied greatly, being most commonly about a fortnight, in a quarter of the cases it was 11 days or less, in a quarter, 12–20, in a third quarter, 21–36, and in the remainder 37–120 The delay in recognising the outbreak was increased by the scattering of the visitors to their homes and difficulties in diagnosing a comparatively rare condition Not more than 20 per cent of cases were correctly diagnosed before it became generally known that a large epidemic of amœbic dysentery had occurred, and the absence of the characteristic diarrhœa and of *Entamœba histolytica* in many cases added to the difficulties An acute onset with fever and abdominal symptoms led to a diagnosis of appendicitis in 16 per cent of the patients who afterwards died, and the fatality-rate in the 32 cases treated by appendicectomy was 40 per cent The most common erroneous diagnosis in the fatal cases was malignant disease, usually of the rectum After a correct diagnosis had been made, the results of specific treatment were very satisfactory indeed the response to a therapeutic test is of great value in establishing the diagnosis[3] The chief interest of the outbreak naturally lies in the epidemiological investigations, which were exhaustive A curious feature was the absence of the enteric fever and diarrhœa usually associated with water borne epidemics The explanation *suggested* is that the chlorine content of the Chicago water supply suffices to prevent survival of bacteria, but not of cysts In a later outbreak among firemen at the Chicago stockyards in 1934,[4] in which the water consumed had escaped chlorination, amœbiasis, enteric and gastro intestinal disorders were all noted Control of the outbreak was attempted by elimination of carriers of cysts from the food handling staffs, but there was no evidence that these efforts were successful However the authors add a caveat "that the experience in this respect is not to be regarded as an indication either of the value or lack of value of the procedure under some other conditions"

By this unique epidemic a new hazard to civil populations has been revealed The United States of America has led the way in personal hygiene and the careful protection of food and drink, *but* the Chicago outbreak of amœbic dysentery shows *that in the end it is sanitation which counts, and* that, as has been consistently taught in this country, an unpolluted water supply must always be the first line of defence Although there is less likelihood of any similar outbreak here, carriers are well known to exist,[5] and one lesson to be learnt is that especial sanitary vigilance is needed in connexion with all water-borne diseases at times—e g, in London at the coming Coronation—when accommodation is strained and weak points in a sanitary system are most likely to be revealed

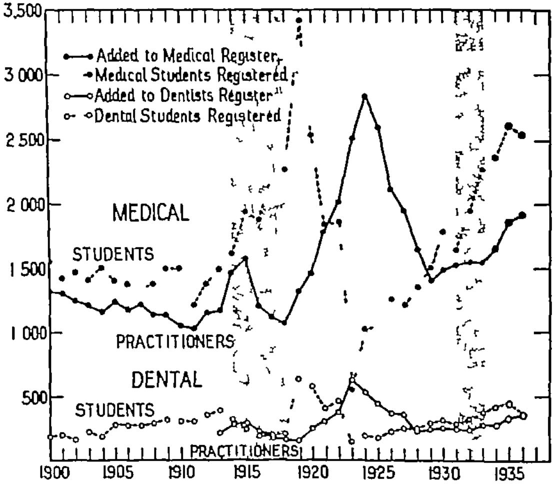
ANNOTATIONS

THE TURN OF THE TIDE

The total entry of students in the medical schools of the United Kingdom and the Irish Free State, as indicated by the numbers registered[1] by the General Medical Council rose steadily (with one trifling exception) during the years 1923–35. The earlier part of this rise was no doubt the mere rebound of the unparalleled entries of 1919–20 but when the pre war norm had been reached in 1930 the rise still continued running closely parallel to the rise in the years 1916–20. The increased entry of 20 years ago was of course related to the war as is shown on the graph in which the period 1915–18 is indicated by a grey band. Last year Sir Norman Walker remarked that in the experience of the Council when trade is bad entries of medical students go up and vice versa. We have accordingly indicated on the graph by a second grey band as a criterion of trade depression the three years in which the average level of unemployed males stood above two million leaving our readers to correlate the two records at their discretion. In 1936 the number of registered medical students was 2544 the decrease of 50 being the resultant of a decrease of 82 in England and 0 in Ireland counterbalanced by an increase of 32 in the Scottish entry. Scotland had in fact the highest entry recorded since 1919 but it is fair to recall the abnormal flow of foreign medical students to Edinburgh as a result of the troubled situation in Central Europe. The Irish entry which has dropped only by a little during the last two years is still as great as in any year since 1920 bearing testimony to the existence of medical reciprocity between Irish Free State and United Kingdom far more real if less documented than the reciprocity with two foreign states. The numbers added to the Medical Register depending as they do on the students entry of five or six years before are still rising: 1905 last year as compared with 1882 in the previous year an increase of 23 small compared with the previous increase of 218 and both in England and Scotland the number has fallen appreciably. That brought the number of names on the Medical Register at the last day of 1936 up to a figure of 59 010. The turn of the tide must bring a sense of relief to British medical schools all of which are as Dr Stanley Barnes remarked a short time ago in Birmingham filled to the limit of capacity. For the first time in the history of the Birmingham school it was found last year impossible to accept some local applicants for places and Dr Barnes foresaw a time in the near future when only matriculated students taking a degree course could be accepted at Birmingham. The decrease is not large enough to give immediate relief nor in Sir Norman Walker's words, will there be any tendency to lower the standard of entry even if numbers do go down a little. The Dentists Register tells rather a different story 470 names were added to that register during 1936 an increment of 133 or 40 per cent on the previous year and far the highest entry since 1925 when there was still a large influx of practitioners registered under the Dentists Act of 1921. Less satisfactory is the decrease in the *number* of students starting on a dental career: 356 in 1936 compared with 436 and 422 in the previous years. This is an entry which may well be regarded by the Dental Board as inadequate to replace the probable wastage of the next decade.



SUSCEPTIBILITY TO RESPIRATORY INFECTION

It is the general experience of mankind and of their medical advisers that the incidence of colds coughs and more serious respiratory infections is by no means random. Some unfortunates seldom survive a winter and early spring without repeated attacks, while a happy few appear to be largely immune. Any observations that serve to throw light on these individual variations in susceptibility are welcome and a series of experiments reported[1] by Dr A Locke from the institute of pathology of the Western Pennsylvania Hospital offer suggestions that clearly merit further study. A series of rabbits were chilled until their rectal temperature had fallen to 95–96° F and a note was made of the time taken to recover 3° in temperature. This was found to vary over a wide range from about 20 minutes to about 125 minutes. Each rabbit was given a rating assessed by dividing 20 by the time actually taken for this temperature recovery. Thus a rabbit that recovered 3° F in temperature in 20 minutes was awarded a rating of unity while one that took 125 minutes was rated as 20/125 (0 16). When an adequate number of rabbits had been rated in this way, one sample of animals were tested by the intravenous injection of a small number of virulent pneumococci, while another sample were subjected to the more severe test of intradermal inoculation Thirty-six rabbits were injected intravenously Of these, 12 had been given a rating of over 0 6, 1 died Of 13 rabbits with a rating of 0 5–0 6, 4 died. Of 11 rabbits with a rating of less than 0 5, all died Fifty one rabbits were injected intradermally Of 16 with a rating over 0 6, 9 died. Of 19 with a rating of 0 5–0 6, 17 died. Of 16 with a rating of less than 0 5, all died. The author then turned his attention to human subjects Sixty eight persons—men, women, boys, and girls—were rated by a different method They were put to work on a machine resembling a stationary bicycle, and their oxygen consumption per minute, per square metre of body surface, was determined during maximal effort After rating they were kept under observation for seven months, and the number of colds contracted by each subject was recorded It was found that those subjects with a high rating developed far fewer colds than those with a low rating These observations are too few to be decisive, but they are at least suggestive

SCHISTOSOMIASIS OR BANTI'S SYNDROME?

We have noted [1] that an illness which seems to be beri beri may in fact be caused by small intestinal trematodes of the family heterophyidæ There is now reason, coming from the four continents, for suspecting, in some at least of the instances of Banti's syndrome, an infection by blood trematodes of the genus schistosoma As Prof Enrico Greppi has pointed out,[2] Banti's view was that in his syndrome the spleen was fibrotic (a fibroadenia pure *and simple is the term used by Greppi*), but Greppi himself reported that in the syndrome as seen by him in Southern Italy and Sicily the spleen was certainly not in a state of pure fibrosis since it lessened in size after the injection of adrenaline He went on to say that E Bucciante, using in Alexandria on persons with splenomegaly from Mansonian schistosomiasis the same tests as Greppi had used in Italy and Sicily on those diagnosed as Banti's syndrome, had had the same findings These findings were an increase in the total plasma—held by Greppi to be a hyperplasia, not a temporary hydræmia—which was still present after splenectomy, a real decrease in red cells after making all allowance for the increase in plasma, no evidence of hæmolysis, and splenic contraction after adrenaline In the *China Medical Journal* for December, 1936, there is a symposium on schistosomiasis, and in it H E Campbell says that the pathological reports he got from two different laboratories on enlarged spleens from persons living near Foochow, Fukien, were consistently "Banti's disease" R C Robertson urged on him that before accepting this diagnosis he must rule out schistosomiasis, and while Campbell was hesitating to settle this during life by removing a piece of liver when taking away the spleen—in fear that this would add to the risk of an already severe operation—he had a visit from Prof H H Loucks of Peiping, who showed him how it might be done simply and safely Of portions of 6 livers of those with this condition (4 taken at biopsy and 2 at autopsy) schistosome eggs were seen in 3—a report which should be put beside that of H B Day [3] on 5 splenectomies for "*Egyptian splenomegaly*" during which he made a small liver biopsy, schistosome eggs being present in all of them Lastly, writing of advanced Mansonian schistosomiasis as seen in Porto Rico, R M Saurez and C M Gautier [4] say of 10 persons, whose sternal marrow they examined after aspiration, that they had splenomegaly and evidence of liver cirrhosis, and that clinically and hæmatologically their condition was indistinguishable from Banti's syndrome Clearly before falling back on this obscure diagnosis in the future, the question of schistosomiasis and its probably hopeful treatment will have to be seriously considered

THE TILT TEST

The functions of the various organs concerned in equilibration are difficult to understand Various attempts have been made to elucidate them, of which that devised by J Tait and W J. McNally of Montreal, however, and described in a series of papers *published during the past ten years, is the study of* an experimental animal deprived of the organ concerned. The success they have achieved in unravelling the complicated inter relationships of the semicircular canals and utricles is largely due to an operative technique whereby, under a dissecting microscope and using a dental drill, they have been able to divide the nerves to each canal, utricle, or saccule without any damage to other structures Dr McNally, in a demonstration to the section of otology of the Royal Society of Medicine on March 6th, described some of the results of these researches, and showed films illustrating the methods by which these results had been produced and analysed

The point of chief importance was the use of the tilt table in testing the reactions of the labyrinth, with a plea for its more common employment in clinical tests If an animal minus its utricles is tilted quickly out of the horizontal, an over compensatory action of the body musculature is produced, and, by further ablations it was shown that the vertical semicircular canals are responsible for this effect By converse experiments, the utricles were found to act by throwing the body further in the direction of the tilt, thus toning down the reaction of the semicircular canals Slow tilting affects the utricles only, and the reaction is compensatory It is not brought into play until some definite movement of the head occurs Thus slow *tilting of the utricles in a certain direction* produces the same effect as rapid tilting of the semicircular canals The two structures are connected in the brain with the same muscle groups, as shown by the similarity of the responses, and by studying the posture and reaction pattern of the muscular reactions in a frog, the exact labyrinthine lesion can be diagnosed. Dr McNally discussed the phenomena in man of nystagmus, past pointing, head turning, and falling, and showed that these movements are really compensatory, similar to the protective movements which resist a sudden tilt This is seen more clearly by tilting the patient when he is on all fours The arms then resist the tilt by buttressing When in the erect posture, the arms resist the tilt by swaying to alter the position of the centre of gravity, much as a tight rope walker uses his pole, and this *movement is away from the direction* in which the patient feels he is falling, but in the same direction as the other compensatory reactions such as head turning Dr McNally believes that if more complete knowledge of the various characteristic reaction patterns of the body musculature on tilting becomes available, the same exact diagnosis of labyrinthine lesions will be obtainable clinically as is now possible in the laboratory The tilt test is simple, and the reactions elicited by it seem to merit study

A COMMUNITY TUBERCULOSIS SURVEY

WITH the support of the Norwegian National Association against Tuberculosis Dr G Hertzberg has recently conducted a community survey of two rural parishes in Norway[1] Thanks to preliminary propaganda and the provision of adequate facilities for expert examinations he succeeded in netting about 50 per cent. of the whole community between five and six thousand persons of all ages being tuberculin tested (Pirquet and Mantoux) and the positive reactors being further examined by the sedimentation test as well as radiologically The radiological examinations consisted of screening and when its findings were positive or ambiguous, of radiography A portable radiological outfit enabled Dr Hertzberg to screen some 200 persons daily at the rate of 30 to 40 per hour and hustling though this rate was comparisons of the findings showed that screening was but little inferior in accuracy to radiography Altogether 120 cases of pulmonary tuberculosis were recognised as such for the first time by this comb-out and in as many as 90 of these cases the disease was caught at an early stage. It was not a little remarkable that 7 cases of pleurisy with effusion were discovered in persons unconscious of being ill The cost of this survey worked out at about 7000 kroner or about 1*s* 3*d* per head It may be noted in passing that such community surveys are at present being conducted systematically in Finland by its National Association against Tuberculosis which has recently equipped itself with 11 portable radiological outfits Dr Hertzberg's stimulating and instructive demonstration is likely to be repeated many times in many places

CEREBRAL ABSCESS

THE treatment of a cerebral abscess is perhaps the hardest task of the neurosurgeon. Accuracy in localisation good judgment as to the moment for operation and critical and untiring attention to post operative details are essentials for success It is widely accepted that radical operation should be deferred if possible until the acute inflammatory reaction has subsided, and until a firm abscess wall has formed During this process however the intracranial pressure may rise sufficiently to endanger life, and various procedures have been recommended to tide the patient over this period based on simple paracentesis of the liquefying area of brain Opinions differ about the correct course to adopt when a well localised abscess has formed Total enucleation is practised by some surgeons others prefer to drain the abscess through a small opening in the skull so as to avoid a fungus cerebri If the abscess is quite superficial success usually follows drainage through an adequate opening in the overlying skull but a much more difficult problem is presented by an abscess lying more deeply in the hemisphere. Operation here carries a grave risk of infection of the superficial healthy brain and of the overlying leptomeninges whereas with a superficial abscess the leptomeningeal spaces are obliterated by adhesions before operation is undertaken For these deeper abscesses E A. Kahn[1] recommends a modification of the King technique relying on a two-stage operation to allow the abscess to migrate nearer the surface, and to obliterate the pia arachnoid spaces by adhesions The abscess is located by exploring with a blunt needle without piercing the wall. A wide opening is made in the skull immediately over it and the dura freely incised Iodoform gauze is packed over the exposed brain and the incision is left open The second operation is carried out several days later when the endothermy loop is used to remove the fungus which has formed The abscess which will be found flush with the skull, is opened and its cavity packed with gauze The intracranial pressure gradually extrudes the remains of the abscess and the packing. Three of four cases treated in this manner recovered Kahn reports these cases in detail which makes his paper the more interesting

VENEREAL DISEASES AND MARRIAGE

IMPROVED means of recognising latent venereal infections have served rather to expose past deficiencies than to simplify the standards by which the cure may be determined. The difficulties are such that the most careful investigation does not remove all uncertainty and the subsequent marriage of the infected patient is never without risk to the marital partner In permitting marriage the physician takes a very serious decision and his natural anxiety is sometimes interpreted by the patient as an admission that the particular disease is incurable. In fact this view is held by many laymen and by some medical men with regard to both syphilis and gonorrhœa. In a review of this difficult and important subject Wolbarst[2] expresses his opinion that there is nothing inherently incurable in these diseases but that they often remain uncured through the fault of the practitioner of the patient or of both. For his own patients with syphilis who wish to marry he demands rigid standards which include 2–3 years continuous combined treatment with the arsphenamines and with bismuth followed by 1–2 years close observation with periodic examination both clinical and serological, to exclude recurrence Tests of the cerebro-spinal fluid must be negative a year after the cessation of the treatment Marriage is permitted to the patient with persistently positive serum tests after prolonged and intensive treatment provided there is no clinical evidence of neurosyphilis and tests of the spinal fluid are negative. Wolbarst throws doubt on his own criteria of cure however by advising that observation should continue for 4–5 years before procreation is considered. There must be evidence that during this period the infected patient has remained clinically and serologically negative and has not transmitted the disease to the partner in marriage He advises that the prospective mother should receive antisyphilitic treatment throughout pregnancy irrespective of which marriage partner was previously syphilitic and if both man and wife have been infected he would have them both permanently sterilised even though treatment may seem to have been fully successful. All patients who have had syphilis are urged to undergo a brief course of treatment once or twice yearly throughout life as an insurance against recurrence To exclude latency of gonococcal infection Wolbarst demands searching clinical and bacteriological examination with repeated tests over a period of several months The presence of numerous leucocytes in the prostatovesicular fluid is taken as evidence of probable infectiousness, but he believes that the most efficient single test is the examination for gonococci of the semen, or prostatovesicular fluid obtained by digital massage, by microscopic and cultural methods He doubts the value of the complement fixation test for gonorrhœa in the blood serum as a test of cure

[2] Wolbarst A L (1936) *Brit J ven Dis* 12 229

While many will not accept these views in their entirety they give a fair indication of the doubts and the hazards that arise It seems that the most rigid precautions will sometimes result in disastrous transference of infection to innocent persons with resulting loss of health and happiness and possible transmission of infection to the next generation It is certain that these responsibilities are sometimes too lightly undertaken, and that even the most elementary precautions are often omitted

THE FACTORIES BILL AND MEDICAL PRACTICE

THE Factories Bill which was introduced by the Home Secretary in the House of Commons on Jan 29th, and read a second time without a division on Feb 15th, is still being considered in Standing Committee We have already dealt in a leading article (Feb 20th, p 451) with the vital question of the adolescent in industry It may now be useful to summarise the changes which the Bill, if it is passed into law in its present form, will make in the work of doctors who are wholly or partially engaged in industry The position of the whole time industrial medical officer remains substantially unaltered except that under Section 11 the Secretary of State may make special regulations for the medical supervision (not treatment) of persons employed at a factory in certain circumstances which have caused or appear likely to cause ill health Temporary arrangements for such supervision may be made without waiting for the inquiry which must precede the issuing of a special order It is possible that this section will provide the foundation upon which a more efficient medical service for industry may be built

Again under Section 119 (3) the Secretary of State may authorise a medical practitioner who is employed by the occupier in connexion with the medical supervision of the factory to act as an "examining surgeon." The appointment and conditions of work of this officer are set out He is to be appointed by the chief inspector (or his district deputy) who also has power to revoke the appointment Appeal against the appointment or against the revocation of an appointment may be made to the Secretary of State No practitioner directly or indirectly interested in any firm can act as an examining surgeon for that firm, except that a medical man employed by a firm may be employed as an examining surgeon if he is authorised by the Secretary of State to do so This proviso raises a point of more than academic interest The examining surgeon from the terms of his appointment is a subordinate official of the Home Office medical staff A medical man employed by a firm might lack (in certain circumstances) that measure of independence and freedom which is essential for the proper discharge of judicial or semi judicial duties The other duties of the examining surgeon are to make such examinations and reports as the Secretary of State may direct, to make an annual report, and to carry out certain duties under the Compensation Acts Upon the question of fees the Bill is silent, except that it provides that they shall be paid by the employer and be determined by the Secretary of State (or by agreement between the surgeon and the employer) Most of the criticisms, just and unjust, which have in the past been levelled against the existing certifying factory surgeon's work have been due to his inadequate remuneration Unless there is improvement in the rate of fees paid for these examinations the other alterations in medical work proposed in the Bill will lose much of their value Under Section 69 the examining surgeon may be called upon to report on accidents and poisonings in industry If full use is made of these powers the surgeons will gain an insight into working conditions which otherwise may be denied them Special examinations of this kind should provide a new source of information about industrial disease and accident

Section 92 governs procedure for the examination of young persons Power is to be granted to the surgeon to issue provisional certificates of fitness (up to 21 days), to call for the re examination of young persons (when necessary), and to request the medical officers of the local education authority to provide confidential reports on the past medical history of young persons in doubtful cases Inspectors are to have power to order the suspension (subject to re examination) of any young person who appears to them to be unfit for the particular work which he or she is doing Moreover power is given to the Secretary of State to prescribe the facilities which must be provided for the carrying out of these examinations It will be seen that in these respects the Bill marks a real advance upon existing conditions of medical work in industry It is essential that the provisions designed to protect the examining surgeon both in his appointment and dismissal should be strong enough to preserve that measure of independence which is necessary to his efficiency

HERMANN KÜMMELL

GERMAN surgery is the poorer for the death on Feb 21st of Prof Kümmell, who occupied for many years the chair of surgery at Hamburg Born in 1852 at Corbach, he qualified in 1875 and in 1883 became associated with the Hamburg Eppendorf Hospital After 36 years of service there the Hanseatic city at last made up its mind to have its own university and Kümmell was chosen as the first professor of surgery His writings cover almost the whole field of surgery and make an impressive list Although in this country his name is associated mainly with the spinal disease that bears his name, abdominal surgery claimed much of his interest In 1890, when appendicitis was still known as peri typhlitis, he was writing about its radical cure Eight years later he was counting 104 recoveries after appendicectomy, and in 1905 he had an experience of 1000 operations He wrote largely on genito urinary surgery, particularly in relation to prostatic enlargement, other subjects he touched ranged from Volkmann's ischæmic contracture to injuries of the *thorax and resection of the colon* "Kümmell's disease" is a late sequel of spinal injury characterised by increasing kyphosis and pain referred along the distribution of the spinal nerves In his original description he attributed these symptoms to disturbance of the local circulation as the result of a rarefying osteitis followed by collapse of the vertebral body Nowadays most of such cases are regarded as compression fractures of the vertebral bodies, which, in the absence of radiological examination, have remained unsuspected, until pressure has caused a slow collapse of the cancellous bone with compression of the emerging spinal nerves

Pott's disease is excluded by X ray evidence of intact vertebral discs and by the absence of suppuration The affected vertebral bodies are typically wedge-shaped Treatment of Kümmell's disease is directed either to the reduction of the deformity by hyperextension followed by fixation in plaster-of Paris, or when that is impracticable to spinal fusion Fusion should include one or two vertebræ above and below the lesion the spinous processes are split and slivers turned up and down to meet slivers from adjacent spines The articular cartilage is sometimes removed from the intervertebral joints and the fusion may be strengthened by insertion of tibial grafts

OBSTETRICS AND THE PREMATURE BABY

PÆDIATRICIANS have been showing a greatly increased interest in the care of the premature baby and in certain centres such as Chicago [1] an intensive campaign has reduced the mortality C H Ingram however writing from the department of obstetrics of the Western Pennsylvania Hospital,[2] calls attention to certain facts which suggest that the obstetrician must not feel satisfied because the pædiatrician has now stepped in He shows that four fifths of the premature babies die in the first two days of life and in his opinion feeding and kindred nursing problems managed now as never before in many institutions cannot be expected to have much influence on these He therefore proceeds to analyse various factors causing death in this period. He found that multiple pregnancy has the lowest mortality rate spontaneous labour coming next There is a relatively higher mortality in the small group of babies prematurely born of mothers with some form of toxæmia of pregnancy while, of course, maternal bleeding yields the highest infant mortality Turning to the type of delivery it was found that of 52 forceps cases only 17 died, the lowest mortality for any method and in contrast with the results in 203 spontaneous live births with a loss of 113 babies Still higher mortalities were found in 23 versions and in 51 breech deliveries. It is concluded from these figures that forceps delivery is the best method for helping the premature baby and in the toxæmia cases it appears that if the mother's disorder is not quickly controlled and if the baby is apparently viable its chances of survival are enhanced if labour is induced by simple rupture of the membranes In prematurity Cæsarean section is emphatically condemned since a baby under 4 lb seems to have only a slight chance of survival. Ingram also clearly indicates that the larger the premature infant at birth the better the prognosis In another section he discusses the autopsy investigations which in contrast to the reports of other workers show that only a small proportion of the babies died from cerebral hæmorrhage Despite this he urges injection of fresh citrated blood intramuscularly to all small babies

CANCER IN CANADA

How far the increase in the death rate from cancer is apparent how far it is real is a question which has been taken up by workers in every country In Canada a study of the available data was made some years ago by Dr Madge Macklin who concluded that in that country cancer had definitely increased [3] Recently she has made a new study of the statistics and compares the position prevailing in 1933 the last year for which figures are available with that of 1901 [4] The increase in the crude death rate is certainly not due only to the increasing age of the population of the country for comparison of the rates age by age shows that both for males and females there has been a rise in the recorded mortality at every time of life Better diagnosis may undoubtedly play a part, especially in the older age-groups in which in 1901 nearly three times as many deaths were ascribed to senility as in 1933 As a correction Dr Macklin tries the effect of considering half the deaths recorded under senility at each date as really due to cancer With this adjustment the cancer death rate still shows a considerable increase at all ages up to 75 but at 75 and over the 1933 rate is only half that of 1901 Probably the method over compensates for the lack of diagnosis in earlier days at these advanced ages. A test that is more usually applied is the comparison of the rates of increase of cancer in visible and invisible sites For the former Dr Macklin takes cancer of the mouth skin breast and uterus for the latter cancer of the stomach liver and intestines Comparison of the rates in 1901 and 1933 shows that the visible has increased proportionately considerably more than the invisible Contrary to results found elsewhere for Canada it cannot be said that the increase lies mainly in those types which are most difficult to diagnose and in which the greatest improvement in diagnosis is likely to have taken place. Dr Macklin herself finds the explanation of the rise in the elimination of other causes of death such as infectious diseases At ages over 35 there would have been in 1933 nearly 11 000 more deaths from infectious diseases in addition to those actually recorded if the 1901 death rates had prevailed, and it is this group within the cancer age, saved from dying of other diseases that causes the increase in the cancer death rate As regards causation this seems to leave us much where we were. If the extra cancer deaths to-day are of those persons whose prototypes would also have died of cancer thirty years ago if they had not been brought to an earlier end by some other disease then the increase is apparent rather than real in the sense that no new causative factors need be implicated The causative factors were the same thirty years ago but were not brought to fruition If on the other hand, more of those saved from other diseases now die of cancer than would have been the case thirty years ago then we must look for new causative factors We have no means of determining which is the true position and so cannot explain this increased death rate at every age

PRINCIPLES OF MEDICAL STATISTICS

XI—LIFE TABLES AND SURVIVAL AFTER TREATMENT

In the assessment of the degree of success attending a particular treatment given to patients over a series of years the life table method is sometimes an effective procedure Before illustrating its application to such data, consideration of the national life tables and the information they contain will be of value A life table, it must be realised, is only a particular way of expressing the death rates experienced by some particular population during a chosen period of time For instance, the last English Life Table, No 10, is based upon the mortality of the population of England and Wales in the three years 1930–32 It contains six columns as follows —

English Life Table No 10 Males

Age x	l_x	d_x	p_x	q_x	$\mathring{e}_x$
0	100 000	7186	92814	·07186	58 74
1	92 814	1420	98470	·01530	62·25
2	91 394	600	99343	00657	62·21
3	90 794	400	99559	·00441	61 62
4	90 394				
102	3 9	2 1	46960	53040	1 32
103	1 8	1·0	44553	55447	1 25
104	0 8	0 5	42115	57885	1 18

The essence of the table is this suppose we observed 100,000 infants all born on the same day and dying as they passed through each year of life at the same rate as was experienced at each of those ages by the population of England and Wales in 1930–32, in what gradation would that population disappear ? How many would be still left alive at age 25, at age 56, &c ? How many would die between age 20 and age 30 ? What would be the chance of an individual surviving from age 40 to age 45 ? What would be the average length of life enjoyed by the 100,000 infants ? Such information can be obtained from these different columns The basis of the table is the value known as q_x, which is the probability, or chance, of dying between age x and age $x+1$, where x can have any value between 0 and the longest observed duration of life For instance q_{25} is the chance that a person who has reached his twenty-fifth birthday will die before reaching his twenty sixth birthday These probabilities, one for each year of age, are calculated from the mortality rates experienced by the population in 1930–32 (for details of method see Woods and Russell, Medical Statistics) This probability of dying is the ratio of those who fail to survive a particular year of life to those who started that year of life (to take an analogy, if 20 horses start in the Grand National and 5 fail to survive the first round of the course the probability of "dying" on that round is 5/20, 15 horses are left to start on the second round and if 3 fail to survive, the probability of "dying" on the second round is 3/15)

The National Life Table

In Life Table No 10 the probability of dying in the first year of life is 0 07186, or in other words, according to the infant mortality-rate of 1930-32, 7 186 per cent of our 100,000 infants will die before they reach their first birthday The actual number of deaths between age 0 and age 1 will therefore be 7 186 per cent of 100,000, or 7186 Those who *survive* to age 1 must be 100,000 less 7186=92,814 According to this table, the probability of dying between age 1 and age 2 is 0·01530, or in other words 1 530 per cent of these 92,814 children aged 1 year old will die before reaching their second birthday The actual number of deaths between age 1 and age 2 will therefore be 1 530 per cent of 92,814=1420, those who survive to age 2 must therefore be 92,814 less 1420=91,394 From these q_x values the l_x and d_x columns can thus be easily constructed, l_x showing the number of individuals out of the original 100,000 who are still alive at each age, and d_x giving the number of deaths that take place between each two adjacent ages p_x is the probability of living from one age to the next p_x+q_x must equal 1, since the individuals must either live or die in that year of life (to return to our analogy if 5 out of 20 horses do not complete the round, clearly 15 out of 20 do survive the round) p_x therefore, equals $1-q_x$, for example, of the 91,394 children aged 2, 0 657 per cent die before reaching age 3, and it follows that 99 343 per cent must live to be 3 years old Finally, we have the column headed $\mathring{e}_x$ which is the "expectation of life" at each age This value is not really an "expectation" at all but is the *average* duration of life lived beyond each age For example, if we added up all the ages at death of the 100,000 infants and took the average of these durations of life we should reach the figure 58 74 years If, alternatively, we took the 92,814 infants who had lived to be 1 year old, calculated the *further* duration of life that they enjoyed, and then found the average of those durations, we should reach the figure 62 25 years At age 102 there are only 3 9 "persons" still surviving and the average duration of life that they will enjoy *after that age* is only 1 32 years The so called expectation of life is thus only the average length of life experienced after each age We thus have the complete life table

To reiterate, it shows how a population would die out if it experienced as it passed through life the same death rates as were prevailing in England and Wales in 1930–32 It does not follow therefore, that of 100,000 children born this year in reality only 90,794 will be alive at age 3, if the death rate is in fact declining below its 1930–32 level, then more than that number will survive if it is rising less than that number will survive The life table can show only what would happen under *current conditions of mortality*, but it puts those current conditions in a useful form for various comparative purposes and for estimating such things as life insurance risks (inherent in the questions that were propounded above)

The Measurement of Survival-rates after Treatment

We turn now to the application of the method to groups of patients treated over a period of calendar years whose subsequent after history is known Let us suppose that treatment was started in 1931, that patients have been treated in each subsequent alendar year and have been followed up to the end f 1936 on each yearly anniversary after their treatment was started (none being lost sight of) Of hose treated in 1931 we shall know how many died uring the first year after treatment, how many ied during the second year after treatment and so n to the fifth year after treatment. Of those treated n 1932 we shall know the subsequent history up to nly the fourth year of treatment in 1933 up to only he third year of treatment and so on Our tabulated results will be let us suppose as in Table XI

TABLE XI

Results of Treatment (Hypothetical Figures)

Year of treat ment.	No of patients treated	Number alive on anniversary of treatment in—				
		1932	1933	1934	1935	1936
1931	62	58	51	46	45	42
1932	39		36	33	31	28
1933	47			45	41	38
1934	58				53	48
1935	42					40

Calculation of the survival rates of patients treated n each calendar year becomes somewhat laborious f the number of years is extensive and has also to be based upon rather small numbers If the fatality rate is not changing with the passage of time there is no reason why the data should not be amalgamated in life table form For clarity we can write Table XI in the form given in Table XII

TABLE XII

Results of Treatment (Hypothetical Figures)

Year of treat ment	No of patients treated	Number alive on each anniversary (none lost sight of)				
		1st	2nd	3rd	4th	5th
1931	62	58	51	46	45	42
1932	39	36	33	31	28	
1933	47	45	41	38		
1934	58	53	48			
1935	42	40				

All the patients have been observed for at least one year and their number is 42+58+47+39+62=248 Of these there were alive at the end of that first year of observation 58+36+45+53+40=232. The probability of surviving the first year after treatment is therefore 232/248=0·94 or in other words 94 per cent of these patients survived the first year after treatment Of the 40 patients who were treated in 1935 and were still surviving a year later no further history is yet known. (If the year's history is known for some of them these must not be added in for the history would tend to be complete more often for the dead than for the living and thus give a bias to the results.) As the exposed to risk of dying during the second year we therefore have the 232 survivors at the end of the first year minus these 40 of whom we know no more—viz 192 Of these there were alive at the end of the second year of observation 51+33+41+48=173 The probability of surviving throughout the second year is therefore 173/192=0·90 Of the 48 patients who were treated in 1934 and were still surviving in 1936 no later history is yet known. As the exposed to risk of dying in the third year we therefore have the 173 survivors at the end of the second year minus these 48 of whom we know no more—viz 125 Of these there were alive at the end of the third year of observation 46+31+38=115 The probability of surviving the third year is therefore 115/125=0·92 We know no further history of the 38 patients first treated in 1933 and still surviving on the third anniversary The number exposed to risk in the fourth year becomes 46+31=77 and of these 45+28=73 are alive at the end of it The probability of surviving the fourth year is therefore 73/77=0·95 Finally during the fifth year we know the history only of those patients who were treated in 1931 and still survived at the end of the fourth year—namely 45 persons Of these 42 were alive on the fifth anniversary so that the probability of surviving the fifth year is 42/45 or 0·93

CONSTRUCTION OF THE SURVIVORSHIP TABLE

Tabulating these probabilities of surviving each successive year we have the values denoted by p_x in column (2) of Table XIII The probability of not surviving in each year after treatment, q_x, is immediately obtained by subtracting p_x from 1 The number of patients with which we start the l_x column is immaterial but 100 or 1000 or some such number is convenient. Starting with 1000 our observed fatality rate shows that 94 per cent would survive the first year and 6 per cent would die during that year The number alive l_x, at the end of the first year must therefore be 940 and the number of deaths d_x, during that year must be 60 For these 940 alive on the first anniversary the probability of living another year is 0·90 or in other words there will be 90 per cent alive at the end of the second year—i e 846—while 10 per cent will die during the second year—i.e. 94. Subsequent entries are derived in the same way (The order of the columns in the table is immaterial. The order given in Table XIII is the most logical while the table is being constructed because p_x is the value first calculated and the others are built up from it In the final form the order given in the English Life Table No 10 of which an extract was previously given, is more usual)

TABLE XIII

Results of Treatment in Life Table Form

Year after treat ment.	Probability of surviving each year	Probability of dying in each year	Number alive on each anniversary out of 1000 patients	Number dying during each year
x (1)	p_x (2)	q_x (3)	l_x (4)	d_x (5)
0	·94	·06	1000	60
1	·90	·10	940	94
2	·92	·08	846	68
3	·95	·05	778	39
4	·93	·07	739	52
5			687	

By this means we have combined all the material we possess for calculating the fatality in each year of observation after treatment and have found that according to these fatality rates approximately 69 per cent of treated patients would be alive at the end of 5 years If we want the average duration of life so far lived by the patients it is easily obtained

687 patients of our imaginary 1000 live the whole 5 years If we presume that those who died actually lived half a year in the year in which they died (some will have lived less, some more, and we can take, usually without serious error, the average as a half), then 60 lived only half a year after treatment, 94 lived a year and a half, 68 lived two years and a half, 39 lived three years and a half, and 52 lived four years and a half The average length of after-life is, therefore (so far as the experience extends) (687 × 5 + 60 × 0 5 + 94 × 1 5 + 68 × 2 5 + 39 × 3 5 + 52 × 4 5) ÷ 1000 = 4 15 years

The percentage alive at different points of time makes a useful form of comparison For instance of patients with cancer of the cervix treated between 1925 and 1934 we find by summarising some published figures in life table form, roughly the following number of survivors out of 100 in each stage of disease —

	Stage			
	1	2	3	4
At end of 5 years	86	70	33	11
, 9	78	57	27	0

EXCLUSION OF PATIENTS

If some of the patients have been lost sight of or have died from causes which we do not wish to include in the calculation (accidents for example), these must be taken out of the exposed to risk at the appropriate time—e g , an individual lost sight of in the fourth year is included in the exposed to risk for the first three years but must be removed for the fourth year If he is taken out of the observations from the very beginning the fatality in the first three years is rather overstated, for we have ignored an individual who was exposed to risk in those years and did not, in fact, die If patients are being lost sight of at different times during the year or dying of excluded causes during the year, it is usual to count each of them as a half in the exposed to risk for that year In other words they were, on the average exposed to risk of dying of the treated disease for half a year in that particular year of observation Clearly if a relatively large number of patients is lost sight of we may be making a serious error in calculating the fatality rates from the remainder, since those lost sight of may be more, or less, likely to be dead than those who continue under observation Complete follow up histories are the desiderata An excellent example of the application of life table methods to the survival rates of patients will be found in an analysis of 8766 cases treated at the Brompton Hospital Sanatorium, Frimley, made by Sir Percival Horton Smith Hartley, R C Wingfield, and V A Burrows (1935, *Brompton Hosp Rep* vol 4)

Summary

Life tables are convenient methods of comparing the mortality rates experienced at different times and places The same methods may be usefully applied to the statistics of patients treated in a particular way and followed up over subsequent years A B H

SPECIAL ARTICLES

SOME PRACTICAL ASPECTS OF MEDICINE IN U S S R

By R H Dobbs, M B , M R C P
FIRST ASSISTANT TO THE CHILDREN'S DEPARTMENT UNIVERSITY COLLEGE HOSPITAL ASSISTANT PHYSICIAN TO THE PRINCESS LOUISE KENSINGTON HOSPITAL FOR CHILDREN AND

Audrey E Russell, M B
MEDICAL OFFICER TO CHILD WELFARE CENTRES, METROPOLITAN BOROUGH OF ST PANCRAS

Much has been written, in books and in medical journals, on the State medical service of Soviet Russia These have made it possible to understand not only the organisation as it exists now, but also the immense difficulties that faced the Government fifteen years ago when there was nothing but an inadequate and primitive medical service disorganised by war and revolution Our object here is to supplement existing publications by recording observations, mainly on maternity and child welfare, made whilst visiting clinics, institutions, and hospitals in Moscow and Leningrad

The primary concern of the medical service in the U S S R is not with hospitals or with diseases and their cures but with the maintenance and improvement of the health of the community The care of the sick and their disposal to hospital becomes a subsidiary function In the public mind the emphasis has thus been shifted away from the idea of disease toward that of health, which in itself helps to promote a healthy society

The medical service of the towns aims at dividing the population into groups of from 40,000 to 100,000 persons, each group in a district being centred around a polyclinic, or prophylactorium These clinics are responsible for all matters concerning health and disease in their districts, and their functions include maternity and child welfare, health visiting, public health services, and sanitary inspection of houses, shops, and public baths, as well as the care of the sick either in the clinic, or in their homes, or by arranging for their transference to hospitals Thus under one institution and under the control of one district director and his staff are centralised functions that in London may be divided between the general practitioner, the panel doctor, the consultant, the local medical officer of health, the voluntary hospital, and the medical services of the London County Council

We visited two such institutions in Moscow The first is one of eleven large new clinics opened in 1930, each of which is responsible for approximately 100,000 of the population It is a building that would put to shame most out patient departments in this country The staff consists of the director and his assistant whose duties are mainly administrative, general physicians responsible for sub sections of the district, specialists in all branches of medicine, and pathologists, together with a full staff of sisters, nurses, health visitors, and sanitary inspectors

The district served by a clinic is divided into sub districts of so many streets and housing approximately 2000 people, and each is under the charge of a district medical officer whose duty it is to attend to ambulatory cases at the clinic in the morning and to visit those confined to bed in their homes in the afternoon A doctor is also available for visiting those needing attention between 9 P M and 9 A M The district officer has the services of the pathology department at his disposal and refers cases needing special advice or treatment to the appropriate consultant, who either sees the patient at the clinic or visits him in his home

At his first attendance at the clinic the patient is seen in his turn and is then given an appointment card, the number of which enables him to gauge within half an hour or so at what time he will be seen at his next attendance. This to a large extent obviates a crowded waiting hall with all its disadvantages On an average working morning in a clinic handling 1000 or more cases a day there is a constant stream of patients coming and going in the entrance hall but no more than three or four waiting outside each consultation room Moreover the clinic is open from 9 A.M to 9 P.M. which reduces congestion further so that each doctor sees an average of only five or six new patients or sixteen old ones in an hour

The impression we received was that the organisation exists primarily not only for the health but also for the convenience and comfort of the patients It is true that the clinic in question has the advantage of modern housing and equipment but it is one of eleven similar clinics already serving 1¼ million people in Moscow and others are projected to replace those housed in old buildings ill adapted to their purpose By a fortunate chance we strayed into a dilapidated old clinic on the outskirts of Moscow where by the courtesy of the German-speaking director we were given the opportunity of observing for ourselves that even under adverse conditions an equally high standard of efficiency is being maintained

Maternity and Child Welfare Service

The antenatal and postnatal maternity services are always considered as one unit and are housed together with the child welfare department the gynæcological department and the department for the teaching of contraception This unit is usually incorporated in a district polyclinic but may be housed separately or be attached to an experimental Mother and Child Institute, and in any case each serves a definite district with no overlapping and all conform closely to a pattern In each department of the unit the walls of the waiting hall and passages are decorated with charts pictures and models giving well-conceived educational propaganda on the problems of the department concerned—on such points as the physiology of conception and normal pregnancy the feeding and clothing of pregnant women and of children the value of fresh air and exercise

CONTRACEPTION

The demand for contraceptive advice is said to be small In connexion with the recent illegalisation of abortion it is of interest to record that according to the doctor at the Moscow polyclinic in the short time since the new laws were passed there has been no increase in the demand for advice on contraception *but there has been an increase in the number of pregnancies* On the other hand we found that this tendency was already apparent before the laws came into force. For instance at this clinic at which are registered over 100 000 persons, the number of abortions dropped from 2247 in 1931 to 1030 in 1934 The number of pregnancies rose from 902 to 1148 while the first attendances at the contraception clinic showed no material change (893 in 1931 and 899 in 1934)

The contraceptive method in favour appears to be a small metal cervical cap which is refitted by the doctor each month A variety of rubber caps and chemicals are also in use

PREGNANCY

As everyone must now know pregnancy in the Soviet Union has ceased to be a social or financial handicap Every pregnant working woman (and 70 per cent of the adult female population in Moscow is at work) has 8–12 weeks leave from work on full pay both before and after the birth of her child. In order to have her doctor's certificate she must in *any case attend an antenatal clinic earlier than the* seventh month of pregnancy but a very large proportion of women come to the clinic much earlier

Antenatal care is conducted on lines similar to those in any London hospital in addition to which excellent educative propaganda in the form of diagrams models and frequent lectures on clothing diet, exercises, physiology and care of the infant is carried out In fact the educative function of the antenatal clinic is organised on a scale unparalleled in this country At the antenatal clinic expectant mothers are told at which hospital they will be delivered and at the onset of labour they present themselves there for admission There is no organisation in Moscow for the delivery of women in their own homes and hospitalisation approaches 100 per cent in all large towns[1] The largest maternity hospital in Moscow the Clara Zetkin of which Prof Blisnjanska is the director serves a number of district antenatal clinics admitting some 6000 maternity cases a year That the standard of maternity care is at least as high as that in similar institutions in this country is shown by the maternal morbidity and mortality figures 15.0 and 1.0 per 1000 respectively The maternal mortality for the whole of Moscow is 2.1 per 1000 that for England was 3.94 per 1000 in 1935

On admission to hospital the patient is bathed and undergoes a general and obstetrical examination The pyrexial cases are admitted to a separate septic block while the apyrexial pass directly to the labour wards of the main hospital. Labour is conducted in two adjacent wards each of ten unscreened beds patients passing from one to the other at the end of the first stage of labour Anæsthesia is recommended for primiparæ and for others when so ordered by the obstetricians A shortage of general anæsthetics has led to the use of a variety of local and basal anæsthetic measures There is however little concession to ideas of modesty or privacy and no small impression was made on us by the sight of seven unscreened women in the second stage of labour and an eighth in the lithotomy position with a recently expressed placenta in a dish beside her One can well imagine the feelings of a young primipara in the early pangs of the second stage involuntarily receiving auditory and visual evidence of what the immediate future holds in store for her[2]

Two hours after delivery the mother is removed to a recovery ward and the baby to a nursery Post-partum care of the mother proceeds along usual lines and includes daily physical exercises and on the final day an instructional lecture on the care of herself and her baby She does not, however have any personal contact with her child except at feeding time until she goes home and has no opportunity of attending to it under supervision In the absence of complications the women get up on the morning of the eighth day and go home on that afternoon A curious defect in the organisation is that arrangements for transport are left to the woman's relatives with the result that some women do in fact walk home alone with the infant

[2] It is only right to add that similar conditions exist in many maternity hospitals in this country

CHILD WELFARE

To an English observer it is surprising to find how large a proportion of women successfully feed their infants on the breast The problem of artificial feeding as we know it in England and America, with its multiplicity of foods and methods, does not exist in the Soviet Union, and the maintenance of lactation gives no difficulty even in the big industrial centres where a large proportion of the women are at work A mother who "loses her milk" is a rarity, and even supplementary feeding is uncommon before six or seven months In the Moscow district polyclinic that we visited, which has on its books 6000 children of 0–3 years, only 10 babies under six months of age were being given supplementary feeds, and these, it may well be noted, were of human milk In another clinic, where 2000 children under one year attended, none under six months were entirely artificially fed, and the director estimated that not more than 5–10 per cent were receiving supplementary feeds In Leningrad, Prof Mendeleevar at the Institute for the Protection of Mother and Child, an experimental clinic to which a large number of difficult cases are referred, estimated that 80 per cent of the babies attending are entirely breast fed at six months These figures are astonishing to anyone who has worked in welfare centres in London, and they contrast sharply with figures collected by one of us (A E R) from a number of welfare centres in North London, where of 980 cases examined only 41 per cent were entirely breast-fed at four months old It is difficult to find an adequate explanation for this difference between the capabilities of the women of the two countries in respect to what should be a natural physiological function The general standard of living and nutrition of the Moscow women and the London working classes do not appear to differ sufficiently to account for it One factor that may play a part is that breast feeding has always been customary among the Russian peasantry, and industrialisation has fortunately not been allowed as yet to interfere with this natural state of affairs The medical authorities accept without question the importance, or rather the necessity for breast feeding, and under every condition of health and social circumstance the mother and her nursling are regarded as one unit From the day of birth every effort is made to avoid any procedure which may prejudice the success of lactation The mother has two months away from her work on full pay before and after the confinement This measure in itself removes any cause for financial and domestic worry On her return to work the mother takes her infant to the factory or office creche and is released from her work for half an hour every three or four hours to feed it Again, illness on the part of the mother or child is not allowed to interfere with the process of breast feeding At the Clara Zetkin Institute, the professor's assistant told us that they recognise no contra indication to lactation whatsoever on the part either of the mother or the child[3] Women with puerperal fever, pneumonia, cardiac disease, and so on still suckle their infants, and only if the mother is severely exhausted is the milk expressed by artificial means and given to the child by bottle The suppression of milk secretion is considered to be an additional strain on a sick woman

In the event of the child falling ill the continuation of breast feeding is still more greatly valued The mother is regarded as a most valuable ally of the medical attendants At the Morozov Clinic, a children's hospital in Moscow, out of a total of 700 beds, 100 are set aside for the accommodation of the mothers of infants admitted for medical or surgical treatment, and one of the most vivid and pleasing memories of our visit is that of entering a small ward in this hospital where a baby recently operated on for a hare lip was asleep in a cot with the mother resting on a bed near to it reading while she waited to attend upon and to feed the child In Leningrad we found that there is adequate accommodation for the mothers at the clinic during the day, but that they return home at night The production of a doctor's certificate of sickness of a child whether at home or in hospital, releases the mother from her work on full pay Lastly, in the few instances where a woman for one reason or another is unable to breast-feed her baby, a supply of human milk is obtainable from the milk kitchens attached to the welfare centres Women with an excess of milk or those in process of weaning their own children are encouraged to come up to the milk kitchen departments and to sell their milk, this they are taught to express under supervision and it is then bottled and sterilised Dried and evaporated milk is scarcely used in the clinics, and there is no dried milk industry as yet established in the U S S R

Weaning is carried out with cow's milk and a variety of starchy and vegetable additions This process has led to the organisation of the milk kitchens which are a striking feature of the Soviet welfare centres, and which form a new and valuable contribution to the problem of supplying the children of an industrial population with properly prepared clean milk and other food These milk kitchens supply one or more district welfare centres, and the output of each is approximately 5000 or more feeding bottles a day Each kitchen obtains its milk from one farm, usually State owned, where collection is regulated and where the herds are tuberculin tested. The milk arrives at the kitchen within a few hours of collection and it is at once cooled, standardised with regard to chemical and bacterial content, and put up and sterilised in sealed bottles either as whole milk, modified or acid milk, or in combination with a large variety of cereal and vegetable products The bottles are set aside in cooled chambers to await distribution to the mothers, who present daily the formula which they have been given by the doctor, and receive the requisite number of bottles made up according to this prescription and ready for the day's feeds In this way each feed is contained in a single bottle and the risk of contamination is negligible

By means of these milk kitchens the diet of a large number of children from six months to three years of age can be controlled and adjusted according to current knowledge of nutritional requirements, and by such an organisation nutritional experiments could be undertaken on an unprecedented scale On the other hand, any defects in the milk diets put out by the kitchens, whether local defects such as some error in one of many processes before the food reaches the children, or a more general neglect of some principle of infant feeding, will be widely reflected in the standard of health and nutrition of the local or general infant community Indeed, we consider that one essential principle of infant feeding is being neglected and that a combination of circumstances has led to a fairly widespread iron deficiency anæmia among the young children (in Moscow at least, where the greater part of these observations were made) We use the words iron deficiency anæmia advisedly as the state of nutrition of the child population appeared in other ways to be satisfactory which indeed would be expected as a result of the methods of infant feeding we have described.

---

[3] But see section on tuberculosis below

The striking and unquestionable pallor of the children under three years of age in institutions and even in the streets is a point that so far as we can discover has not been commented upon nor has the question of iron deficiency anæmia been investigated or recognised At no hospital, creche clinic or even experimental institute would any doctor agree with us when we suggested that some of the children were suffering from this type of anæmia We were told that anything over 65 per cent of hæmoglobin is accepted as normal, but it is clear that many of the children fall short of this standard Our impression was supported by figures shown to us at a creche in Moscow where of 67 apparently healthy children of one to three years of age the average hæmoglobin level (Sahli) was 50 5 per cent (lowest 27 per cent highest 64 per cent) Four of these children had hæmoglobin levels below 40 per cent

In this country iron deficiency anæmia is looked upon as an indication of a state of under nutrition and a widespread anæmia amongst the child population of Moscow and Leningrad is at first sight at variance with the indubitable fact that the mothers are so very successful at providing the ideal food for their infants, and that the health authorities apparently provide more complete welfare supervision for the infants than we do in this country We sought therefore, to discover some adequate explanation for this apparent paradox by determining at what point the infant population is receiving inadequate supplies of iron

The infant receives a store of iron during fœtal life that has to last it until it is given some food containing more iron than does human or cow s milk We have no direct evidence pointing to the existence of anæmia among Russian women nor could we find that blood analyses have been done on a large scale upon pregnant women The following points however are at least suggestive Meat has only become at all plentiful during the last year or so Before 1936 it was often unobtainable at any price The position with regard to green vegetables is similar but less striking Certain it is that for the four or five years previous to 1936 the diet of the general population was such that iron deficiency anæmia was most probably present Such few figures as we were able to obtain taken at random from the books of the polyclinic showed that the average blood count of women attending the clinic for a variety of diseases was red cells 4 380 000 hæmoglobin 69 per cent (Sahli). We can say therefore that in all probability children six months of age at the time of our visit in September 1936 were born of women who for the past ten or fifteen years have been getting a diet deficient in iron The methods of weaning practised in Russian clinics also have some bearing on this question At the District Polyclinic in Moscow children are breast fed for about seven months or longer if the child was premature vitamin additions being given from three months From seven months rice flour is given with a cow s milk mixture at eight months fruit juice (grape) is added and not until ten months is any iron containing food given At the Institute for Mother and Child Protection at Moscow meat juice is given at eight months We were told by a doctor working in a small outlying clinic that of her seven colleagues two were pre revolutionary in training and kept the babies under their care on breast-milk alone up to twelve or fourteen months There thus exists, in the low iron store at birth in the late weaning which is fostered to a great extent by the very success in breast feeding that we have commented upon and in the excessive use of cereal foods deficient in iron such as rice barley and fruit juices a combination of factors predisposing to iron-deficiency anæmia in young children Furthermore, the facts that even with otherwise adequate food iron in some form is needed by the infant at an early age and that anæmia increases susceptibility to infection do not appear to have yet been recognised in the Soviet Union The director of a Moscow polyclinic when he agreed that some of the extremely pale children might be suffering from some degree of anæmia asked whether after all it was of any great consequence Questions relating to treatment were answered in terms of ultra violet light fresh air good food extra vitamins and medicines containing phosphorus and calcium specifically to improve bone growth. More often than not, iron was omitted from the suggested treatment These facts provide some basis for the criticism which is sometimes levelled at the medical science of the Soviet Union that during its rapid general advance progress has lagged behind unaccountably in many directions This is not surprising and is scarcely avoidable since this progress has taken place in circumstances of comparative isolation due partly to the language difficulty and partly to the historical events of the past twenty years

Tuberculosis

Before the revolution little or nothing was done to deal with the problem of tuberculosis although it did, and still does, rank highest in the list of fatal diseases The death rate per 10 000 in Russia in 1913 was 22 per 10 000 Since 1920 when the death rate in Moscow from tuberculosis reached the high figure of 39·7 per 10 000 a nation wide campaign has been fought against the disease with the result that the figure was lowered to 11 6 per 10 000 in 1931 [4] and 9 7 per 10 000 in 1935 Of recent years this campaign has been intensified and we think that the efforts made in so far as children are concerned are worthy of a special note.

The milk for general consumption is sold in dairies and comes by way of the milk factories from collective farms whose herds are not tuberculin tested and many of whose cows are therefore presumably infected At the factory the milk is inspected pasteurised and bottled In addition a certain amount of raw uninspected milk is sold in the open market by individual peasants The milk kitchens attached to the district child welfare centres which supply a very large proportion of the child population up to three years of age in the big towns, receive milk each day from their own State-owned farms At some of these farms the herds are regularly tuberculin tested but this is not done universally, At the milk kitchen the milk is sterilised as we have already described, in order to prevent the spread of tuberculosis and other bacterial disease amongst the children

Another feature of the fight against tuberculosis which is apparently unique to the U S S R is the institution of night sanatoria, to which attention has frequently been drawn [5, 6] To these institutions which are attached to the regional tuberculosis dispensaries, children with "weak chests" or whose home conditions are particularly bad are sent to spend the night and be provided with two good meals. They go to school as usual during the day. A second group of children come during the day and return to their homes at night. In this way many children, though not ill enough to be sent away, can yet for several months spend half their time under medical supervision in hygienic surroundings and be assured of adequate nourishment. Night sanatoria for adults are run on the same lines.

[6] Newsholme A., and Kingsbury J A (1934) Red Medicine London p 247

Lastly, in common with a number of other countries, the U.S.S.R. is using B.C.G. vaccine for the immunisation of infants born of tuberculous parents. Women attending the tuberculosis dispensaries who become pregnant, and those attending district antenatal clinics who are found to have tuberculosis, are carefully supervised at the dispensaries, and provided the disease is quiescent are allowed to come to term normally. When the baby is born, it is given B.C.G. vaccine by mouth before the tenth day, and meanwhile is allowed to feed at the breast. Women with open tuberculosis who become pregnant are either advised to have an abortion or are sent to the Clara Zetkin Maternity Hospital in Moscow. This institute receives all such cases from Moscow and a wide surrounding district. Every woman is there immediately admitted and her condition investigated by a panel of three doctors, consisting of a chest specialist, an obstetrician, and a pediatrician, and the most suitable treatment is devised to suit the case. The woman is then sent to spend the rest of her pregnancy in a sanatorium, returning to the Institute to be delivered. When the child is born it is immediately separated from the mother for the first ten days of its life, while it is immunised by the oral administration of B.C.G. vaccine. Meanwhile lactation is encouraged by artificial means, and the milk fed to the infant. At the end of ten days the child is returned to the mother, and both spend a further period at a sanatorium. During the past few years 1270 women with tuberculosis (95 per cent. with pulmonary tuberculosis, 14.6 per cent. with positive sputum) have been treated in this way and their babies immunised with B.C.G. vaccine. The infantile mortality in the first year of life was 117 per 1000 (as compared with the figure of 120 per 1000 for the whole of Moscow); only two children died of tuberculosis, one not having been immunised.[7]

The authorities in Moscow claim that the results of this experiment are already encouraging, as is indicated by the figures above which were given to us by the director of the Institute, and it is intended shortly to extend this immunisation to cover all infants born, irrespective of the state of health of the parents. By this procedure it is hoped eventually to reduce the incidence of tuberculosis among young children to negligible proportions.

Medical science in the Soviet Union has produced much that is admirable both in theory and in practice. The most noteworthy and characteristic achievement has been a fundamental change of viewpoint from a preoccupation with the study of disease to a realisation of the far greater importance of the maintenance and improvement of health. The outcome of this realisation has been the establishment of a national medical service which is designed to deal with all aspects of the health of the community and in which emphasis is laid on preventive measures. In the large towns, and in those departments of medical science with which we are familiar, this service appeared in practice to be satisfactory both to the individual and to the State. An immediate advantage of such an organisation is that health measures approved of in principle can be rapidly put into effect over a large proportion of the population. The scope for research on a national scale appears to be almost unlimited, and it is going forward in many branches of medicine.

It is of great interest to the visitor to study the advantages and disadvantages of a State health service developed on logical lines on such a comprehensive scale, and we are grateful to the many doctors and officials whose kindness and patience helped us to follow the working of this medical service, of which the Soviet Union is justifiably proud.

INTERNATIONAL BIOLOGICAL STANDARDS

ON a previous occasion[1] we gave an account of the history and development of the work of the Permanent Commission on Biological Standardisation of the Health Organisation of the League of Nations. The current number of the Quarterly Bulletin[2] records the progress made during the past two years, during which time standards for three of the sex hormones, for gas gangrene antitoxin (histolyticus), and for diphtheria antitoxin for use in the flocculation test have been adopted. During the period it has been necessary to make certain changes in regard to some of the standards which have been in use for many years.

Insulin

Partly on account of the fact that the original insulin standard established in 1925 is now exhausted and partly because that standard has become progressively less suitable for the assay of the increasingly pure insulins of commerce, a new international standard for insulin has been provided by the Commission. The standardisation of this important remedy, the safe and effective application of which depends so much upon accurate dosage, was put upon secure foundations in 1925 by the adoption of an international standard and the definition of a unit. The original standard was prepared from the purest insulin available at the time, and for many years it served its purpose. With the advent of the highly purified insulins of commerce, however, it was observed that small but definite differences in potency were assigned to pure preparations according as to whether the assays were carried out by the use of rabbits or of mice, when the comparison was made directly with the relatively impure standard. The reason for these discrepancies is not at present fully known, but the fact that they occur and, moreover the fact that samples of pure crystalline insulin have activities which are indistinguishable by whatever method they are assayed, led to the decision to adopt, as the new international standard a preparation of the purest insulin obtainable; 51 grammes of such a highly purified insulin was prepared by Dr. D. A. Scott of the Connaught Laboratories, Toronto and, through the generosity of the insulin committee of the University of Toronto was placed at the disposal of the Commission with a view to its adoption as the new international insulin standard The next problem was to assay the new standard in terms of the original one—in effect to determine the weight which had the same activity as one-eighth of a milligramme of the original standard which, since 1925 had represented the unit of insulin activity Comparative tests were carried out by three independent investigators in Canada three in England one in Denmark and one in the United States of America The discrepancies already referred to were again revealed in the evaluation of the new standard in terms of the old using the rabbit as the test animal, the average value of the new standard was 21 5 units per milligramme while the average value by the mouse convulsion method was about 25 units per milligramme The results of the determinations of the experts were subjected to critical examination by a small conference consisting of Sir Henry Dale Prof C H Best and Prof A Krogh. They gave reasons why it was not possible to decide upon the unit value of the new standard solely on the basis of the values returned but taking into consideration all the data and available information and the views of the individual members of the conference the Commission decided to accept the new standard for international use and redefined the unit of insulin as the specific insulin activity of one twenty-second of a milligramme of the new standard It is stated that no appreciable change or at most a fractional change in the direction of a slight increase in the value of the unit is involved in the decision now taken Further it is pointed out that the difficulties which have been encountered in the present inquiry are unlikely to recur that the value now accepted for the unit of insulin in terms of the new standard is likely to be final and permanent and not subject to further uncertainty or possibility of even a fractional change if replacement again becomes necessary and that the standard itself being a pure crystalline substance is susceptible to periodical control in comparison with new samples of freshly prepared insulin.

[1] *Lancet*, 193 , i, 68 .

[2] *Quart. Bull. Hlth Org. L.o.N.*, Biological Standardisation Spec. No., November, 1936.

Digitalis

The original international standard digitalis powder established in 1926 now being practically exhausted a new standard preparation has been adopted by the Commission Replacement in this case has been relatively simple In 1928 a large quantity of dry powdered digitalis leaves was prepared in England accurately assayed in terms of the international standard and adopted as the British standard digitalis for use in connexion with the British Pharmacopœia Recent comparative tests have confirmed the earlier evaluation of the potency of the British standard and an assurance having been obtained of its stability and suitability for use the Commission decided to adopt the British standard preparation as the new international digitalis standard Adequate quantities of the preparation have been placed at the disposal of the Commission by the National Institute for Medical Research Hampstead where it is maintained for international distribution

Posterior Lobe Pituitary

In 1925 an international standard for posterior lobe pituitary was established and a small quantity of standard powder was available for the assay of national standards No laboratory however has hitherto been officially entrusted with the care and distribution of the posterior lobe pituitary standard In England a quantity of dry posterior lobe pituitary powder equal in activity to the small sample referred to above has been in use as a national standard since 1925 Moreover since the National Institute for Medical Research has, for many years distributed this standard to workers in many countries the Commission decided to adopt as the international standard of pituitary extract, the posterior lobe pituitary powder prepared at this institute and to request it to hold and distribute the standard on behalf of the Health Organisation The Commission took the further step of defining a unit of antidiuretic activity in terms of the international standard. The position has now been reached therefore that the standard maintained at Hampstead is now officially adopted as the international standard for the assay of the active principles of the posterior lobe of the pituitary and the unit of oxytocic, pressor and antidiuretic activity respectively are defined in terms of this preparation. It is pointed out that when the present standard has to be replaced it will be necessary to make a fresh determination of the relation in which the oxytocic pressor and antidiuretic actions stand to each other and if necessary to redefine the units in terms of which those three actions are expressed.

Arsphenamine

In 1925 international standards for six arsphenamine (arsenobenzene) derivatives were established and, until recently all of these except sulpharsphenamine were maintained at Frankfurt for international distribution. Circumstances have arisen which necessitate a new arrangement whereby these standards can be made available for international use and the Commission has accordingly entrusted the National Institute for Medical Research with the preparation preservation and international distribution of the standards of the arsphenamine group The standard for sulpharsphenamine has been maintained at this institute and distributed therefrom on an international basis since 1928 and present indications are that it will only be necessary to maintain international standards for arsphenamine neoarsphenamine and sulpharsphenamine

The total number of international biological standards established by the Commission is now 27 Of these 12 are standards for antitoxins antisera and old tuberculin and are maintained at the State Serum Institute Copenhagen and 15 are standards for drugs hormones and vitamins and are maintained at the National Institute for Medical Research At these two institutes the standards are available for supply to laboratories and research workers throughout the world Reports from these institutes deal with the preparation care and preservation of the standards and the administrative procedures adopted to bring them into effective use They draw attention to the increasing demand for the standards and emphasise the need for the establishment of a national centre or centres in each country [2] in order that simplification and economy of administration may be effected the widest possible application of the standards ensured and research work in the field of biological standardisation facilitated and advanced

PARIS

(FROM OUR OWN CORRESPONDENT)

THE CRISIS IN SILK SUTURES

THE recent history of the vicissitudes of the silk suture industry was given at a meeting of the Academy of Medicine on Feb 16th by Dr E Perrot and Dr P Bruère Though the prospect of the supply of silk sutures from Spain being cut off owing to the civil war is the immediate cause of the alarm felt in France at present, the question of making the country independent of foreign supplies is many years old The term applied to surgical silk, "crin de Florence," owes its origin to the fact that certain natives of Tuscany emigrated into the valley of the Rhone, bringing with them the industry of fishing silk This was first introduced into France for the benefit of fishermen in 1760, and it was not till 1877 that Trélat found such silk suitable for ligatures in surgery Soon after the late war the question of manufacturing surgical silk was submitted to a special commission, and in due course a model organisation was set up at Alès (Gard) All went so well that by 1930 the home product was found by experts to be quite equal in quality to the imported article, and for a time it looked as if French made surgical silk had come to stay, but at this stage a dismal concatenation of circumstances upset the whole scheme At the present time the surgical requirements of France every year amount to more than two million silk threads, 1,400,000 being required for the civilian population and for export, 500,000 for the Assistance Publique, and 100,000 for the army It was calculated in 1925 that a million threads per month would be required by the army on mobilisation

ARE EXAMINERS HUMAN ?

The recent publication of letters in the medical press on the subject of examinations, examiners, and examinees is a reminder that the problem does not begin and end with "satisfying the examiners" The examinees and their parents must also be satisfied, more or less, not to mention co examiners or assessors Prof Pierre Mauriac[1] has unburdened himself on this subject with disarming frankness and in the spirit of a co examiner rather than in that of the examiner himself Is, he asks, strict impartiality possible ? Then he startles his readers by asking if it is even desirable He seems to wish to endow the examiner with a certain latitude in the matter of the personal and moral qualities of the examinee, thus the anonymous examination may not be altogether suitable The reform of the examiner must come from the examinee, and though, in Prof Mauriac's opinion, the examinee may be ill qualified to appreciate the scientific merits of his examiners he is the *best judge of their value as teachers* Among the peccant examiners pilloried by Prof Mauriac is the one who must needs drag in his specialties and expect the examinee to know all about them Another type is he who wanders from his own to other fields, coquetting with medicine if he is a surgeon, and committing "howlers" damaging to his reputation *Prof Jean Delmas*[2] has described yet another kind of examiner who is all out for orthodoxy, giving full marks for the text book mentality, and to whom individuality and independence of thought are anathema It seems from this discussion that the impersonal, machine minded examiner is inhuman, and his erratic, fad loving colleague is even more execrable, and one wonders if the difficulty could not best be met by the appointment of a board of super examiners composed of examinees This is what Prof. Mauriac implies is already the case, but in an informal way

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

BICENTENARY OF THE ROYAL MEDICAL SOCIETY

DURING the week ending Feb 27th the principal celebrations in connexion with the bicentenary of the Royal Medical Society have taken place, and a large number of senior members from all parts of the country attended. The presidents for the year are Dr A G Ross Lowden, Dr R F Dawson, Dr J M Macfie, and Dr A S Crawford, and on Feb 25th they held a reception in the society's premises, which gave senior members the opportunity of inspecting the many improvements that had recently been carried out in the buildings and in the library At the annual dinner on the same evening about 250 were present.

Dr Robert Hutchison proposed, as the toast of the evening, The Royal Medical Society It seemed, he said, to have been robust from its start and it had never looked back Before it had reached its fiftieth year it had built a hall and received its Royal Charter and it had begun to collect a library The modest sum that the society aimed at collecting in celebration of its bicentenary was still far from being reached. Surely the present members would not allow themselves to be out-done in zeal by their forefathers The society succeeded where others had failed because it must have proved itself complementary to the education of the class rooms and the *infirmary* It provided a means of self expression—a safety valve by which the student might blow off as much steam as he liked. The medical student, and never more so than to day, was like the Strasbourg goose he was crammed with facts until he got fatty degeneration not, it was true, of the liver, but, what was worse, of the brain Argument and refutation, ridicule and laughter were the aids to mental digestion, and these the Royal Medical had always provided in abundance Dr Hutchison added that he believed that the most important principle in the training of doctors was expressed in the old saw "you can't have the terriers too soon at the rats"—in other words, you cannot bring the student too soon into contact with the patient Finally, the Royal Medical satisfied the need of the student for the society and intellectual companionship of his fellows It had survived many troublous times, it had seen the '45, the loss of the American colonies, the French Revolution, the Napoleonic wars, the comparative peace of the Victorian era, and the catastrophe of the late war The present times held a new threat to intellectual life in the suppression of free discussion in other countries There was all the more need, therefore, for those societies in which intellectual freedom was the breath of life

Dr Ross Lowden, *the senior president*, said that he intended to send a telegram of greeting to the society's oldest member, Sir James Crichton Browne, who signed the obligation in 1858 He reported that the society was in a flourishing position with 66 new members in the year The bicentenary endowment fund now totalled about £1800, and though the sum aimed at was £3000 it is to be hoped that steps could be taken to preserve the most valuable old books in the society's library

A VOICE FROM THE GRAND STAND

Sir Auckland Geddes formerly a president of the Royal Medical Society gave an address on Feb 20th to a crowded meeting of the society at which Dr Ross Lowdon presided Sir Auckland Geddes said that for many years his path had lain far from the profession of medicine and that he felt like a spectator who on the strength of a precarious membership of his school third XV forty years ago, shouted advice and criticism to the international players The more he had seen of life and death of pain and suffering the more clearly he had realised however that there was never in the real world outside the walls of the medical school and teaching hospital a disease to be treated or an injury to be dealt with: there was just a sick child woman or man to be helped to get well. He had gradually gained the impression that on average young doctors had surprisingly little understanding of man and the medical profession had been losing something of the public s respect and trust The real business of clinical medicine was not science; it was a personal relationship into which much sincerity and medical knowledge were suffused by the physician and trust and some dependence by the patient In this respect there seemed to be a lag in progress at present in the preparation of the medical student for no amount of scientific knowledge unless it be subordinate to understanding the individual, could make the medical man a true healer far too often a doctor attending patients had irresistibly reminded him of a vet attending sheep He thought this was because too many were being demoralised by panel practice and because too many came to the sick room thinking of themselves as men of science fighting disease and not as healers with a little knowledge helping nature to get a sick man well. Beyond their scientific knowledge of man lay an incompletely explored area in which important things happened without discoverable physical cause In spite of the brilliant record and achievement of science they must realise the fact that to day science was running into blind alleys from which it can only emerge by escaping from direct touch with human understanding. They could not grasp man as a whole but this did not mean that it was impossible to improve their understanding On the contrary once they had ceased to fear what seemed to them non rational and recognised that human reason could not grasp all reality they could get to know a good deal about man

TREATMENT OF TABES DORSALIS

Dr Robert Lees gave some observations on the treatment of tabes dorsalis at a meeting of the Medico Chirurgical Society of Edinburgh last week. He analysed the results of treatment in 200 patients who had been observed for a period of not less than two years and all of whom had been treated at the Edinburgh Royal Infirmary He excluded any cases in which the diagnosis was in doubt The routine examination in each case included clinical examination especially of the nervous system and examinations of the blood the cerebro spinal fluid the optic discs the fields of vision and the urine and teeth especially for evidence of local sepsis Several of the patients in the series have been attending the department for as long as 15 years. There were 81 per cent with a positive Wassermann reaction in the cerebro spinal fluid but after two years treatment 73 per cent. of these showed a definite improvement. In general the serological and clinical response appeared to be parallel but there were some patients with negative findings but severe clinical symptoms All cases that became negative under treatment remained negative when it ceased. The treatment consisted of the administration of tryparsamide intravenously and bismuth intramuscularly Both injections are given at the same time and in courses of weekly injections for ten successive weeks, with an interval of one month when the course is repeated The maximum benefit was seldom obtained in less than two years and sometimes not for five. After the treatment is completed the patient is asked to report every 3–6 months for an indefinite period Very few complications or toxic effects were observed; the danger of toxic amblyopia has probably been exaggerated and Dr Lees does not hesitate to treat cases of optic atrophy with tryparsamide He reported that in patients with tabetic pains there was definite improvement in 75 per cent; in 16 per cent these were unaffected while in 5 per cent they became worse As regards ataxia, 65 per cent improved 6 per cent. became worse, and the remainder showed no change. In two cases of rectal crises the results were very satisfactory Charcot s joints occurred in 4 per cent and the treatment appeared to benefit the general condition of these patients. There were definite signs of optic atrophy in 12 per cent of the series Tryparsamide therapy was carried out with the careful coöperation of ophthalmologists who observed the state of the visual field All methods give poor results with this condition, but both in the present series and in a series previously investigated by the late Dr David Lees 50 per cent. of those treated did not progress to complete blindness Cases of juvenile tabes usually respond well to treatment. Finally Dr Lees concluded that the treatment carried out was justified by the satisfactory results obtained In his opinion a very prolonged period of treatment and observation is essential

---

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED FEB 27TH 1937

Notifications—The following cases of infectious disease were notified during the week: Small pox 0 scarlet fever 1019; diphtheria 1252; enteric fever 45; pneumonia (primary or influenzal) 1372; puerperal fever 53 puerperal pyrexia, 107; cerebro spinal fever 15; acute poliomyelitis 4; acute polio-encephalitis, 2; encephalitis lethargica 8 dysentery 21; ophthalmia neonatorum 71 No case of cholera plague or typhus fever was notified during the week.

Notifications of acute pneumonia were much below expectation: in London 39 per cent below; in the country as a whole 16 per cent below

The number of cases in the Infectious Hospitals of the London County Council on March 5th was 3353 which included: Scarlet fever 858 diphtheria 1037, measles, 30 whooping cough 584 puerperal fever, 17 mothers (plus 10 babies); encephalitis lethargica 283 poliomyelitis 3 At St Margaret s Hospital there were 19 babies (plus 8 mothers) with ophthalmia neonatorum

Deaths—In 122 great towns including London there was no death from small pox 4 (0) from enteric fever 7 (1) from measles, 5 (1) from scarlet fever 31 (10) from whooping-cough 28 (1) from diphtheria 43 (11) from diarrhœa and enteritis under two years and 212 (23) from influenza The figures in parentheses are those for London itself

Of the 204 deaths from influenza in the great towns of England and Wales outside Greater London the largest totals were reported from Liverpool 17 Manchester and Birmingham each 11 Newcastle-on Tyne 10 Corresponding figures for Scottish and Irish towns were Edinburgh 5 Glasgow 9 Dublin 6 Belfast 6

Leeds Liverpool Birmingham and Bristol each had a single death from enteric fever Hull reported 2 deaths from measles Fatal cases of whooping-cough were scattered over 19 great towns: Leeds reported 3 Birmingham 2 Fatal diphtheria was reported from 22 great towns: 3 from Liverpool 2 each from Manchester and Sheffield

The number of stillbirths notified during the week was 277 (corresponding to a rate of 13 per 1000 total births) including 30 in London

GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations Each contributor is responsible for the section for a month, his name can be seen later in the half yearly index

FROM A RUSTICATING PATHOLOGIST

III

Dr Carrel's "Man the Unknown" is a strange book. In manner it is thoroughly up to date for there is no *continuum* it proceeds by quanta and school children who were set to parse it would have to get out of their difficulties by classing a good proportion as "exclamatory" And it is said to have been a best seller in America It will be interesting to see whether it has the same popularity here still, our literary tastes are peculiar, are we not said to be the only people who find *Punch* funny? But in whatever style he writes, Dr Carrel succeeds in getting his meaning across as well as many other people, and it is naturally with the meaning that we are concerned Knowing something of his laboratory work on tissue culture, the healing of wounds and suchlike matters, we should have suspected or even been convinced that he was one of those austere men of science who hold that the real truth is bounded by what can be ascertained by exact quantitative experimentation, indeed, it has seemed perhaps sometimes that his passion for meticulous preciosity in method has taken up more of his attention than the results he has been after What is so interesting about the book is that it reveals him as quite a different kind of man. As one would expect, there is much excellent exposition of what may be called conventional scientific knowledge about the body and its tissues But he goes far beyond this He is prepared to believe in what he cannot understand, which has commonly been supposed to be the mark of the loose minded fellow in contrast to the real scientist The most scientific scientists of course believe, perhaps inadvertently, in some things which they cannot understand—e g, gravity—and may hold that some result is the effect of a cause when they cannot trace the intermediate steps But this is not considered in general quite the right thing to do Yet Dr Carrel (see particularly his chapter on "Adaptive Functions") is frankly teleological, the body reacts in such and such a way to changes in itself or its surroundings in order that it may reach a certain end, the tissues behave in short as if they were sentient human beings A number of people who have looked at the known facts with such honesty as they could muster have come to the same conclusion and it is likely enough that it is as near the truth as we can get, at any rate just now, *I believe myself that the most fruitful* way of looking at pathological reactions is from the end which they aim at or reach, but the point of view is unconventional, and it is interesting to find it in Dr Carrel most people still hold that what the body does is determined by the mechanisms which are available, and it is *not long since the late regius* professor of physic in the University of Cambridge declared that neo vitalism died with J S Haldane Going further still, we find that Dr Carrel believes that intuition is a valid method of scientific discovery, and says "clairvoyance and telepathy are a primary datum of scientific observation" though the phenomena are exceptional and elusive and cannot be reproduced at will, he also agrees that some miraculous cures are effected at Lourdes, though seldom This open minded attitude on matters to which orthodox science is commonly wholly indifferent or hostile seems to me admirable, if only because it may stimulate more detailed investigation In fact there is a great deal to be said in favour of his nonconformity There is a book of which all I remember is that it was bound in black and was by a Scotch presbyterian minister intimate with Kelvin and Tait and other *great discoverers of his time,* which argued that scientific progress seemed to depend on something very like the messages from Heaven received by the Old Testament prophets And intuition is obviously important, however it comes about, it may be the unconscious summation of knowledge and experience, it may be a capacity to hear a still small voice, but whatever it is, it works Telepathy too appears to be simple fact of experience, uncontrollable, useless, not very interesting And if a blister with all the classical phenomena of local inflammation can be produced by suggestion, as it undoubtedly can, it is not inconceivable that prayer may be helpful in getting sick people cured, as Dr Carrel thinks And he is, as he says in the preface, a man of science

* * *

Dr Carrel deals as much with questions of opinion as with questions of fact And his readers' confidence in his opinions would be the stronger if they could feel quite sure of his facts It is difficult to avoid a certain amount of doubt He says for instance that "we know that in countries where water is rich in calcium, the skeleton becomes heavier than it does in regions where the water is quite pure" Do we? Is it really true that people who drink the almost distilled water supplied *to Glasgow have* lighter skeletons than the corresponding Londoners whose water contains 20 or 30 times as much calcium? If it were, it would be strange, for the water we drink is not the main source of the body's calcium And the hygienist may well ask where is the elysium when the water is "quite pure" Or again "It is remarkable that mental diseases by themselves are more numerous than all the other diseases put together one person out of every twenty two has to be placed in an asylum at some time or other" What does it mean? At a modest computation 21 9 out of every twenty two people suffer from some other disease at some time or other But of course all persons with "mental diseases" are not detained in institutions, which really take notice of disorders of conduct rather than disorders of mind, if a man walks down the street every day whistling "Slippin' round the corner" he can still go free as a respectable citizen, whereas if he goes without his trousers he will probably be shut up Is it both or neither or which that is afflicted with mental disease? *Dr Carrel would do well to reconsider his terrifying statement,* which frankly is not the sort of thing that we have learned to expect from a man of science" or from the Rockefeller Institute, not because it is questionable but because its meaning is quite obscure Or *take this piece of voluptuous fiction* "Moral sense is almost completely ignored by modern society Those who discern good and evil, who are industrious and provident, remain poor and are looked upon as morons Artists and men of science supply the community with beauty health and wealth. They live and die in poverty and so on for about a page. What a fantastic travesty of a world permeated all through with goodness and kindness and justice—yes, even in New York—and where even most scientists are not at all badly paid One might as well say that No Mean City is an accurate view of a cross section of the citizens of Glasgow It is perhaps right to accentuate the existence of the few bad and the more foolish people there are in the world because they want dealing with but to brand all men as robbers because of a few thieves or all women as loose living because of a few prostitutes is the negation of all that science has ever stood for Man has a natural passion for righteousness just as he has a natural passion for knowledge and the vast majority of mankind tend to do good in so far as it is known to them Without these natural qualities education would it seems to me be futile we cannot alter man fundamentally our business is to make the best of what is there It is with shame that I recall and recite a rebuke I had not so many years ago

Jones was extraordinarily nice about that business I said, and the answer came Why do you think so badly of him ? Isn t it quite ordinary for people to be nice ? *Of course it is and perhaps it is just a* general realisation of this that leads to the worser daily papers (and to some extent also the best) and the News Bulletin copyright reserved that comes over in that honeyed voice and Dr Carrel to draw such a horrid picture of the world what is normal and customary has no news value Similarly people glorify the past and talk of the good old days which I have no doubt were on our present standards as bad as bad could be. It is entirely false for example to suppose as many people seem to do that our ancestors built better houses and made more durable furniture than we do to day What they rightly admire is the selected few examples which survive; the majority of houses built 200 or 300 years ago have disappeared altogether because they were intolerably bad most of those which are still here are poor places to live in—damp dark with ill fitting doors and windows for living in rather than looking at they are nowhere near the council houses of the last 20 years So too with the body We hear a great deal of physical degeneration and the evils of coaxing unwilling infants to survive but judging the past as best we may it seems clear that the people of this country are now more fitted to live human lives than they have ever been before my mother wore a cap and sat in a chair at an age when my wife does a good day s gardening and enjoys it Look at the amount of illness people say yes, but look at the change of standard Hospitals used to be places for people to die in and the doctor was summoned as the last resort in a desperate situation he is sent for now if the patient has a suspicion that he may be going to be ill to morrow which is why there are now more doctors and busier ones than there used to be and at the same time on the same criterion less illness The present is indeed very much better than the past and the intellectual and moral gain is as great as the physical. Some of my friends are very loath to believe that people now are better than they were but it seems to me one of the most patent facts of experience that during my own life time there has been a substantial increase in the virtues which I can perhaps best sum up as disinterestedness—unselfishness kindness generosity toleration The reason for it I would not try to make out but there it is and it is a pleasing and encouraging thing to think about It is as nasty and depressing to reflect that we are no doubt accepting many things as tolerable or even admirable which in another generation or two will be recognised as abominable our sins and negligencies are bad enough but I suspect that our ignorances are far worse.

* * *

All this reminds me of some strange talk that has been about in recent years about what is called the impact of science on society Presidents of the British Association and others have gloomily wondered whether man s morals are up to coping with the powers which science has placed in his hands they suggest that unless we destroy science, science will destroy us and propose that there shall be a ten years holiday from further scientific discovery to give us a chance to recover our equilibrium. What they really seem to mean is that it is a pity that engineer s brains should go into bombing aeroplanes and motor cars which facilitate large-scale burglary or that chemists should spend their energies on poison gas but they express themselves and perhaps actually feel the situation in more general terms, and there seems to be some chance that nervous ladies will be looking under their beds for scientists as well as communists. There is in short a feeling about that science is something to be afraid of It is hard to understand why we have known for a long time that it was one of the attributes of God to tell the number of the stars and call them all by their names The current feeling seems to come in the main from two misconceptions.

* * *

The difference in the machinery of our lives which has been made by scientific discovery in the last forty years is in general greatly exaggerated and the unfortunate hyperbolic habit of talk which has grown up is always finding that some pretty ordinary event is an unparallelled situation or an unprecedented crisis and the world the Empire the church and what not are always arriving at cross roads the places where suicides were buried and where black cats had their throats cut on Friday nights to get blood to cure warts Do we not grossly over estimate the importance of what happens in our own time ? Aeroplanes motor cars and wireless are noisy and *dramatic* but do they really represent more than quantitative improvements on ships which could sail against the wind hard roads and the old semaphore which itself was not much quicker than the method of throwing a message wrapped round a stone from hand to hand ? We can hardly doubt that these things are genuine improvements: the pictures of heaven which men have drawn differ in detail but they *all* agree that time and space are abolished and anything which helps towards this ideal is welcome But they do not seem more dangerous than most of the other improvements which man has made—sharp knives the possibility of keeping cattle alive through the winter on cabbages and roots the rotation of crops steam engines and all the rest Everyone of these can be used to promote the ends of bad as well as of good men If people want to kill one another they will use the best means that are available and if these are denied them they will use the next best and so on What [illegible] all so much is to realise that men of ill will [illegible] a splash in the world for this [illegible] is in no way to blame and to wipe it [illegible] prevent its further progress would have not [illegible] effect

* * *

And the existence of men of ill will [illegible] difficult to avoid Men have always dreamed [illegible] knowledge would be complete and when everyone would be good. But the ideas are illusory the world is not made in that way, comfortable as it would be to think so The horizon of goodness, like the horizon of knowledge, fades for ever and for ever as we move, what was good yesterday may be bad to day, and what is good to day may be bad to morrow It is not long since murder was nothing more than a civil offence against the dead man's relations, lying was so little condemned that if it was profitable to the liar it counted as a virtue and so it is now in some savage tribes, unkindness was not one of the seven deadly sins, it was as lately as June, 1785 that Thomas Clarkson rode down the hill to Wadesmill beyond Ware and resolved to devote his life to the suppression of slavery as the monument there commemorates And the course of the evolution of our moral sense is certainly no haphazard series of accidents, for it has always run in the direction of realising that what was thought good is actually bad usury is the only exception I can think of There are therefore at any one time various human actions about which there is a difference of opinion bull baiting is bad, fox hunting is doubtful, drunkenness is perhaps just about ceasing to be doubtful, gambling is doubtful and I remember Webb saying in a Fabian lecture "I wonder when we shall have a stop in the mind about living on rent", J L Paton said that unpunctuality was a sin because it was selfishness and some people (including myself) think that the Zoo is not at all nice If we include other countries than our own the range of opinion about right and wrong becomes much wider Hence good and evil are relative to the prevailing conditions and there is no more prospect of a state of existence in which there is no evil than there is of one in which we know everything Quite likely man is, on the average, always about the same distance from the ethical horizon which he can see, some get nearer than others and the laggards are the bad people who make such an impression on Dr Carrel It all follows from the "Origin of Species" and the normal curve of variation

---

CORRESPONDENCE

THE DANGERS OF OVER-STATEMENT

To the Editor of THE LANCET

SIR,—Are we not becoming too violent in our language when we criticise treatment of the past while advocating new methods? Thus I read in your journal to day "Failure to apply this treatment is tantamount to criminal neglect" Conduct, be it noted, that not only lays the practitioner open to damages in a civil court but also should be punished by imprisonment In his memoirs Mr J A Spender tells how as he became experienced with leading articles he found himself writing the more moderately the more strongly he felt on the subject in hand. It is a pity, therefore, that language so strong, which could never be supported in either a civil or a criminal court, should be used to damage a good cause

Those who have, from time to time to act as mediators in cases of a quasi judicial nature in a committee of doctors and of medically minded laymen will realise how hard it is to weigh the pros and cons of any complaint in the face of a statement such as this How much more difficult it must be when it is a question of defending a case in a court of law in which the obiter dicta of the great carry so much weight On this occasion you were quoting the words of a surgeon whom to day we all respect and a teacher from whom we all have learnt May I, however, point out that there seems to be a growing tendency in your journal to make statements in a phraseology which is more dogmatic than the judicial nature of the anonymous editorial chair seems to warrant Thus in August last (1936, 2, 270) you wrote in an annotation, ' The advantages of basal narcosis for children are undoubted, whatever opinions may be held with regard to the same procedure for adult patients This is a hard saying for one who is beginning to wonder whether these same drugs give all the advantages they are reputed to do, and whether, except under the rarest circumstances, they should ever be used in children Again in a leading article on Dec 5th last (1936, 2, 1339) you wrote that " it has become an imperative duty to employ them [i e, a new proprietary drug or its substitute] in severe forms of streptococcal infection" Before reading Dr Colebrook's article in your journal of that date I had not heard of such drugs In the last twenty years many proprietary drugs have been put on the market that were to cut short the illness in streptococcal infections and that have all proved valueless We may therefore forgive the senior members of the profession if they do not rush at every new one that comes along One might rewrite the sentence thus "It looks as though, at last, a drug has been discovered that may help us in the management of the severer forms of streptococcal infection" But we should not criticise any experienced practitioner who, faced with a problem that he knows he has a good chance of solving, refrains from using a drug that may so alter the course of the disease that it disturbs his judgment in the management of the patient It is not until these drugs have been proved to act with the certainty of diphtheria antitoxin in the treatment, or of typhoid inoculation in the prevention, of an infective lesion that we should use the word imperative in reference to them Are we, for instance, certain that so strong a word should be used even for the exhibition of quinine in malaria or the arsenical compounds in syphilis?

May I therefore urge that, while we should keep in touch with youth by understanding and even sharing in their exaggerated terminology in our lighter moments, yet we should, in our practice and teaching of medicine, retain a balance of expression and the use of words in meanings that they have come to hold and not in those weaker ones that they may bear in the future

I am, Sir, yours faithfully,

London March 6th T B LAYTON

⁂ Sir David Wilkie's words were "The profession has never sufficiently recognised the value of the contribution made by Bier, in the shape of passive congestion, for such infections I would go so far as to say that to omit the use of passive congestion, in acute infection with lymphangitis, is to be guilty of criminal neglect" An advantage of strong statements of this kind is that they arrest attention and in welcoming Mr Layton's wise criticism we are glad to remember his own ability to shock his readers into thinking for themselves —ED L

MANIPULATIVE SURGERY

To the Editor of THE LANCET

SIR,—As I know demands upon your space are numerous perhaps my esteemed friend Mr Blundell Bankart, will forgive me if I confine myself in this letter to what is the all important question as to whether I do or do not cure true recurrent dislocation of the shoulder by my methods of manipulative surgery? Mr Bankart criticises Case No 1 in Mr Rowley Bristow's report of the demonstration I gave at St Thomas's Hospital on July 22nd last Here is the full story

This patient wrote me as follows on July 11th, 1936: In 1921 I dislocated my right shoulder and this has continued to recur at intervals which have recently become frequent I have consulted several doctors who have told me that there is no cure and that the state of my shoulder must be regarded as permanent'

I afterwards saw this gentleman and selected his case for demonstration first because of the length of time his disability had lasted secondly because of the great number of times the dislocation had occurred; and thirdly because of the unanimity of the verdict of the several doctors that his case was incurable

He told me that the first time the shoulder dislocated the pain of reduction was excruciating but that each successive time the dislocation recurred the pain of reduction became less he never was able to reduce the dislocation himself but relied on the skill of a friend who became very expert

I performed my first and only manipulation on this patient under gas anæsthesia at St. Thomas's on July 22nd 1936 before about a hundred members of the British Orthopædic Association and immediately afterwards made him do movements calculated to test the shoulder to its utmost. The joint stood the trial perfectly neither in the amphitheatre nor in the ante-room later was any suggestion put forward that the case might be other than one of true recurrent dislocation On Sept 7th six weeks after my manipulation the patient wrote My shoulder has given me no trouble of any kind in spite of the fact that my exercises have not been very regular and that I have bathed several times, executing the side stroke and over arm two feats of which I was formerly incapable I feel that I owe you a very deep debt of gratitude

On Sept. 16th this patient was re examined by several surgeons at St Thomas's Hospital and confirmed the above statement and added the joint was 'perfect Not until then was it suggested that the case might not be one of true recurrent shoulder dislocation after all! I at once said that if this is not a case of true dislocation what other disability is there which so closely resembles such a condition and which "several doctors would describe as incurable? I then turned to one of the hospital surgeons standing by and said Have you a case of recurrent shoulder dislocation in the wards? He said, Yes The patient was brought up I examined and questioned him before the surgeons As he was a hospital patient I asked if they were fully satisfied that the case was one of true recurrent dislocation of the shoulder They said they were and I asked if I might operate at once The permission of the patient having been obtained gas was administered and I dealt with the case On Sept 24th 1936 10 days after my operation this patient wrote: My shoulder has not given me any trouble " On Oct. 10th he wrote: So far I have not had any trouble with my shoulder at all On Nov 12th he wrote Up to the present my shoulder has given me no trouble at all On Feb 2nd, 1937 he wrote: So far my shoulder has behaved excellently and has given no trouble at all.

In these two cases the first has only had two or three relapses in eight months against frequent dislocations—sometimes daily—in fifteen years whilst the second has had no further trouble at all. Both patients I believe will be completely and permanently cured judging from my former experiences in such cases I am Sir yours faithfully

Palace Hotel, Jersey March 8th	HERBERT BARKER.

CHEST LEADS IN ELECTROCARDIOGRAPHY

To the Editor of THE LANCET

SIR —I have read with great interest the two papers and the annotation in your issue of Feb 27th. It is certainly most desirable that the method of applying the electrodes should be standardised and that as soon as possible to avoid needless confusion in an already complex subject

The preference expressed in your columns for the method used by Drs Willcox and Lovibond will naturally carry great weight, and deserves careful consideration But there is much to be said for the retention of the original method of leading used by Wolferth and Wood and by Wilson (*Heart* 1933 16 153) the method which is almost universal in the United States and which I note has been adopted in recent work from Vienna published by Freundlich

Drs Willcox and Lovibond state that the fourth lead can be made to conform to the conventional standard leads by simple reversal of the electrode connexions This is true in a clinical sense—i.e as regards the general form of the normal tracing—but it should be realised that chest leads differ radically from the standard limb leads The potential variations are led off in the latter from points which are far and approximately equidistant from the heart the points of attachment of limbs to trunk serving roughly as the angles of the familiar Einthoven triangle In chest leads however one electrode is much nearer the heart than the other and as Willcox and Lovibond rightly state the anterior electrode is dominant in virtue of its proximity to the contracting organ There is thus a fundamental difference between a standard lead electrocardiogram the algebraic sum of potential variations of equidistant points and the chest lead electrocardiogram which reflects particularly the potential variations under the anterior electrode No modification of technique can render them truly comparable, though a specious resemblance may be achieved.

Further in physiological studies such as those of Craib and of Wilson it is usual to apply the electrodes to strips of muscle, &c. in such a fashion that activity under the 'exploring electrode causes upward deflection of the string—i.e the right-arm contact of the string is led off from the muscle the left arm contact from a distant or indifferent point. Such leads were used by Wilson and his collaborators in an investigation of experimental coronary occlusion by chest and direct leads in 1932 From this work it would appear that using Wood and Wolferth's technique the rapid swing-over from negative Q to positive R (well seen in Fig 1 of Dr Freeman's paper and in Fig 1c of Drs Willcox and Lovibond's) denoted arrival of the excitation wave below the anterior electrode—that is corresponded to the intrinsic deflection of Lewis in direct leads from the muscle. As this deflection denoting activity below the anterior electrode is *upward* when the R A contact is on the front of the chest, the Wood Wolferth technique seems to parallel most closely the leads used in physiological work That such a parallel is desirable needs no pleading, for in the last resort our understanding of these deflections, like all our electrocardiographic lore, depends on correlation with physiological experiment

The question thus is one of considerable complexity, and a decision once reached will prove of importance to a great body of clinical and other workers I question whether a decision in favour of either method could be reached with the facility suggested in your last issue, and I think that the matter is one which might well be referred to a representative body of cardiologists for settlement

I am, Sir, yours faithfully,
IAN G W HILL.

THE CONSOLIDATED WORLD RESEARCH SOCIETY LTD

To the Editor of THE LANCET

SIR,—I have read with much interest your article under the heading Medicine and the Law Hire Purchase Research, in THE LANCET of Feb 6th, as my society, the London and Counties Medical Protection Society Limited, has for a considerable period dealt with a number of complaints by its members against the Consolidated World Research Society Ltd Not only has it advised its members to discontinue its subscriptions to the Consolidated World Research Society Ltd, but has offered to defend them should proceedings be brought, and in collaboration with its solicitors has repeatedly invited the Consolidated World Research Society to take proceedings, but in no instance has this challenge been accepted This challenge is still outstanding and will be accepted whole heartedly should the opportunity occur

I am, Sir, yours faithfully,
C M. FEGEN,
Secretary, London and Counties Medical
Protection Society Ltd

FINGER-PRINTS

To the Editor of THE LANCET

SIR,—Your annotation (p 523) on Wolfgang Abel's observations gives me the opportunity to raise some controversial points Specialists in a number of different ologies are now using finger prints as a tool and in some instances misusing them. Abel's work is the sequel of a laborious series of investigations, carried out in Norway for the most part but confirmed elsewhere, designed to throw light on the interaction of heredity and environment in the formation of papillary patterns Bonnevie, to whom we owe most of our knowledge, some four or five years ago reached the following position, and after checking various references in Abel's paper I believe it still holds good [1]

Only three Mendelian couplets are involved A factor, VV, governs the thickness of the epidermis in early embryonic life, thick skin is dominant to thin, and the heterozygote is intermediate Two other factors, RR and UU, govern the formation of epidermal pads on the radial and ulnar fingers respectively Presence of pad is dominant to absence of pad, and the heterozygotic condition leads to thin pad Three systems of ridges occur a system starting at the nail fold and growing over the top of the finger a system starting at the joint fold and spreading distally, and a system beginning in the middle of the ball of the finger at the point where two twigs from the lateral digital nerves meet These three systems meet at the so called triradius or delta, and can readily be identified by a glance at the finger tips except in the case of the triple dominants who may have no loops or whorls but only arches in which case no delta exists

The endless variety of finger prints comes about in a curious fashion The effect of high pressure in the connective tissue of the finger ball is to expand the finger tip into a ball, which is perfectly regular so long as the epidermis is of even thickness and elastic And the triple recessive accordingly sometimes shows regular whorl or loop formation on all fingers In most instances, however, the nerve twigs meet more to one side than the other, and pad formation, when it occurs is also slightly asymmetrical The whole mechanism is obviously highly unstable and easily affected by various external influences Abel now brings forward evidence, in confirmation of various experiments of Bonnevie, that generalised as well as localised changes of pressure can occur in the finger tips, which may actually burst the embryonic epidermis and lead to changes obviously recognisable in later life

This apparently wayward erudition has a very practical bearing on medical research

Stocks [2] in 1930 claimed to be able to separate twins in nearly every instance, into identical and fraternal pairs by means of their finger prints No special acquaintance with the problems of twins or of heredity or of finger prints was shown in the paper, presumably because the author thought it unnecessary to the development of his argument The two weak points of the paper, as Stocks himself realised, were firstly that the criterion of resemblance of the finger prints was entirely subjective, and secondly that no evidence was advanced that an accurate division of the material into identical and fraternal pairs had in fact been made The second point is unimportant and I do not stress it To return to the first point, everyone knows the rough classification into whorls, loops, arches, but the difficulties of intermediate forms are not so widely realised Galton at one time invented as many as 53 different categories, and Bonnevie prophesied that a continuous series might eventually be found In practice the expert see the differences and the inexpert the resemblances Stocks apparently can control his judgment fairly well He writes "A pair of finger prints were classed as similar, when they were not merely of the same class (arch, whorl or loop) but so much alike as regards general configuration, inclination of axes, position of deltas and numbers of ridges, as to make them appear the same to a casual examination without actually counting the ridges or looking for minutiæ" In other words, Stocks managed to keep his eyes sufficiently half shut to identify identical pairs with the same Mendelian composition Other observers however with an equally large material at their disposal have been unable to utilise Stocks' methods without other aids Theoretically too the method is unsound Especially in an inbred area, one must expect to meet with fraternal twins from time to time with the same U V R genetic formula, while owing to the frequent anastomosis of the placental circulations in identical twins, considerable differences in their intra uterine environment occur This is of course the explanation of why Siamese twins so seldom resemble each other These points have been clearly realised by interested biologists for a number of years, and so when it became necessary to look for points to classify twins, characteristics involving a large number of different Mendelian factors comparatively stable against environmental influences were sought for There is sufficient evidence that the methods employed by the Kaiser Wilhelm Institut für Anthropologie which is aiming at a complete follow up of all German twins and has an enormous material at its disposal are accurate and it is a pity that English observers do not report interesting cases in a form which makes them reliable evidence for the world literature.

---

[1] See Abel W (1930) *Z Morph Anthr* 36 1 for literature

[2] Stocks P (1930) *Ann Eugen, Camb* 4, 59

Lastly might I add a few words on the point of twin research? Anyone who has the chance to investigate half a dozen identical pairs of twins where one member has a consistently higher blood pressure than the other member of the pair or where arterio-sclerosis, gastric ulcer diabetes allergic disease or any other common disease has an asymmetrical incidence learns far more about the practical ætiology and prevention of the disease than any laboratory worker or hospital specialist. Twin research is the only method of distinguishing between hereditary factors intra uterine factors and postnatal factors. That is why these enormous efforts are being made in Germany to clarify the biology of twins. We may be able to adapt German X ray apparatus, endoscopical instruments and drugs to our purpose but their twin results will not be applicable, because the two unknowns involved in the sum Heredity × Environment in this country are obviously different.

I am Sir yours faithfully

RADIOGRAM AND RADIOGRAPH

To the Editor of THE LANCET

SIR,—The varying opinions expressed in your correspondence columns (Jan 23rd to Feb 13th) show that unanimity of choice is not possible as far as the words in present use are concerned and it is obvious that none is completely satisfactory. Your stated preference for the word *radiogram* however is a tangible point, and in my opinion a disturbing one, and I am addressing you on behalf of the British Institute of Radiology to urge you to reconsider your decision as to the use of that word.

The etymological points having been exhaustively reviewed I should like to confine myself to the question of usage. Although the word *radiograph* actually appeared first in medical literature *radiogram* was not far behind it and forty years ago their chances of survival were practically equal. Very soon however the *radio telegram* made its appearance and was most reasonably shortened to *radiogram*. The word has been in use in that sense ever since and the fact that the same word has lately been adopted as a contraction for *radio gramophone* makes it still less desirable to try to bring it back into medical phraseology.

The word *radiograph* on the other hand has been used by most radiologists and many of their colleagues ever since as a contraction for what the general public calls an *X ray photograph*. It is by no means an ideal word especially as it may also denote "an instrument for recording intensity and duration of sunshine." There can be no doubt however as to which of the two meanings is more generally understood. If a better word than *radiograph* could be coined it would be very acceptable but there appears to be no valid reason for discarding it for a word which has nothing more to recommend it and which is already in general use under an entirely different meaning. There is something to be said for *X radiograph* but it is clumsy and would almost certainly be shortened to *radiograph* before long.

I brought this matter up for discussion at last month's meeting of the medical committee of the British Institute of Radiology which considered that nothing had occurred to alter the opinion which it recorded in November 1934 when the following resolution was passed. "After discussion it was unanimously agreed that in referring to the photographic product of an X ray examination the word *radiograph* should be used both as a noun and as a verb in the same way as the word *photograph* is used. It was pointed out that this is correct according to the Oxford Dictionary."

I am Sir yours faithfully

p-AMINOBENZENESULPHONAMIDE IN BACTERIAL MENINGITIS

To the Editor of THE LANCET

SIR,—We have shown that *p* aminobenzenesulphonamide has a protective action in meningococcal infection of mice (*Lancet* 1936 1 1286 1937 1 16). In the second of these papers evidence was adduced that the drug appears in the cerebro-spinal fluid of rabbits after oral administration. A small inoculum of streptococci failed to grow in the fluid of the treated rabbits whereas a similar inoculum grew in the fluid taken from the untreated controls. Recently Dr Fuller (*Lancet* 1937 1 194) has designed a chemical method for the detection of the sulphonamide in the blood and urine of treated animals. By applying this method it is possible to show that *p* aminobenzenesulphonamide, given orally appears in the cerebro spinal fluid in remarkably high concentrations. For example a rabbit weighing 3 kg was given 3 grammes of sulphonamide by the mouth; four hours later 1 ml. of clear cerebro-spinal fluid was removed from the subarachnoid space and a blood sample taken. The amount of sulphonamide in the cerebro-spinal fluid was 0 2 mg per ml. and that in the blood was 0 3 mg per ml. The concentration of the drug in the cerebro spinal fluid is thus 1 in 5000 which has been found sufficient to exert a strong bactericidal effect on the streptococcus in our in vitro experiments with human blood and on the meningococcus in culture medium. This observation illustrates the remarkable ease with which the drug diffuses through the body, and appears to justify the oral administration of *p* aminobenzenesulphonamide in the treatment of bacterial meningitis.

ROYAL MEDICAL BENEVOLENT FUND

To the Editor of THE LANCET

SIR,—It may be of interest to your readers to have a brief summary of the results up to Dec 31st 1936 of our special centenary appeal.

During April 1936 we posted to 44 604 medical practitioners (at a cost of £500 10s) an appeal signed by Sir Thomas Barlow president of the Fund together with an Historical Review of the Hundred Years Work of the Fund compiled by Sir Humphry Rolleston. The centenary fund was opened by the very generous lead of Sir Thomas Barlow who made a gift of £1000 which has been followed by 596 donations amounting to £3570 11s 7d. It was noted that of these 596 donations no fewer than 337 were from subscribers who already gave annual contributions and only 259 donations were from those who had not previously supported our benevolent work. In addition to the above after the despatch of the 44 604 appeals 117 practitioners signified their wish to become annual subscribers to the amount of £149 10s , and a few old subscribers increased their subscriptions, adding a further £23 12s to our annual income

The administrators of the Fund felt that the response from the profession as a whole had been somewhat disappointing, and consequently decided to send out a reminder to the appeal. In November, 1936, at a cost of £65, 6523 letters were posted to practitioners in the postal districts of London who were known not to be subscribers to the Fund and each was asked for a small contribution, such as an annual subscription of 5s To these letters 286 replies were received, and 220 of the recipients signed banker's orders, thereby becoming annual subscribers of a further £101 5s

Our committee has decided to keep the centenary fund open until April, 1937, when the centenary year will have ended. A reminder is being sent this month to every practitioner in England, Scotland, and Wales who has not yet responded to the appeal. We earnestly beg of your readers who are not already subscribers to fill in the banker's order for 5s as soon as they receive this final appeal which will reach them in the course of the next few days

We are, Sir, yours faithfully,
D'ARCY POWER,
Chairman of Committee
LEWIS G GLOVER,
Honorary Treasurer

PROTAMINE INSULIN

To the Editor of THE LANCET

SIR,—The announcement from four British firms in your last issue that a preparation of protamine zinc insulin of British manufacture will now be available in this country is of great interest to everyone occupied with the treatment of diabetes , it is, however, desirable to emphasise the mild words of warning included in the letter announcing its appearance on the market

The new insulins have come to stay Their slower action not only enables the physician to reduce the number of daily doses in many cases, but reproduces more exactly the theoretical manner of insulin secretion in health , it is probably on this latter account that so many patients report a considerable improvement in their general feeling of well being when the new products are employed But in some instances the change over to one of the new insulins is the herald of a period during which insulin reactions may be frequent and sometimes severe to the point of danger , for this reason the change should only be made when the patient is under close medical supervision, and unless this rule is strictly observed the introduction of the new products may result in major or minor catastrophes liable to mar the record of a most valuable advance in therapeutics

Having employed protamine insulin for many months I am convinced of its immense value, but I am also familiar with the serious difficulties which must arise when any potent drug is introduced with an action sufficiently slow to carry with it the risks of cumulative effect When such a substance has the further property of being variable in its potency owing to changes of the amount held in suspension in different conditions, and of being liable to alteration when slightly contaminated by sterilising fluids, it is clear that considerable care is required in its administration

For these reasons I feel it necessary to express a warning as well as a welcome in this letter

I am, Sir, yours faithfully,
London, W March 8th T IZOD BENNETT

A REVIEW OF GOLD THERAPY

To the Editor of THE LANCET

SIR,—In their article in your last issue Copeman and Tegner write " Other observers (Douthwaite 1936, Pemberton 1936, Hartfall and Garland 1935) have recently reported series of cases successfully treated by means of gold salts, and certain of these express the opinion that such general reactions far from being harmful are almost an essential to success." There is considerable ambiguity in this remark and I, as one of the observers mentioned (the reference, by the way, is incorrectly quoted—it should be 1935), would say that it is not my opinion that the toxic features which may appear during gold treatment have any relation to the ultimate success of such treatment as I did say in the article to which these authors refer Further, it is stated that there is general agreement that the use of gold salts in osteo arthritis may be harmful I would dissent from this, for at the moment I am finding them an increasingly useful remedy in this condition , and I hope shortly to publish my results

I am, Sir, yours faithfully,
Liverpool, March 6th H S PEMBERTON

ANALGESIA IN LABOUR

To the Editor of THE LANCET

SIR,—The following case of temporary sterility followed by a normal labour under modern methods of analgesia presents points which may be of general interest, the patient being herself qualified and in medical practice

At age 34, after five years' married life, she was admitted to hospital for lipiodol injection and radiography The first injection showed tubes of abnormal outline and doubtful patency , and three small opacities in the position of the left ovary The second injection under greater pressure appeared to open up the tubes and the radiogram showed lipiodol in the peritoneal cavity and the outline of a dermoid cyst, the three opacities being teeth The potential risk of torsion and possible effect as a deterrent to pregnancy were considered adequate grounds for removing it The cyst was found to be inseparable from the left ovary and the mass was removed in toto , a blood cyst was excised from the right ovary, whose covering was abnormally thick , and a pathological appendix was removed at the same time

Five months later two injections of 1 c cm Antuitrin S were given at intervals of 36 hours at the beginning of a menstrual cycle , the second produced distressing symptoms suggestive of hypoglycæmia, but not the desired result Six months later again four injections of 0 25 c cm were given at intervals of three days, and pregnancy occurred the following month

A first labour at 36 in a patient with a history of rickets in childhood and only moderate muscular development suggested careful watching in the later stages of pregnancy, and Cæsarean section was discussed , however, the child's head engaged satisfactorily and labour was allowed to proceed naturally, although its onset occurred a fortnight after the expected date It began at 3 A.M with a show, and the membranes ruptured at 11 30 A.M , but pains were not evident until five minutes after an injection of Pitocin at 12 30 P M At 2 30 they were beginning to be uncomfortably strong and thenceforth until the end of the first stage patient inhaled 30 per cent N_2O in air from a Siebe Gorman apparatus at every pain For 5½ hours this gave complete relief without affecting the frequency or effectiveness of the uterine contractions and between pains she was able to read and even enjoy a tea party At 5 P M there was barely one finger dilatation At 8 P M the pains began to be so strong as to occasion some discomfort even with the apparatus in action , nevertheless the time seemed to her to pass very quickly as she slept between pains At 10 P M , the beginning of the second stage, gas, oxygen, and ether were given by an anæsthetist at first intermittently; this was less satisfactory because owing to the degree of pain needed to wake her from the anæsthetic administered during the previous contraction she had not time to warn the anæsthetist of the onset of the next one and consequently felt each pain acutely and she found the other very unpleasant So she was after a short while kept under continuously and the baby a girl weighing 9¾ lb was born at 12.20 A.M Forceps were used rather to control the head before crowning than because tractive assistance was needed There was no damage whatever either to mother or child The mother had remained lying down throughout labour she did not even brace her feet against the foot of the bed and pull on a towel or bear down." She did in fact nothing but inhale the analgesic at every pain Twelve hours later she was sitting up in bed enjoying a good meal, and feeling perfectly well without any stiffness or discomfort whatever

To sum up the points of note are (1) an unsuspected dermoid cyst diagnosed solely by radiography (possibly the first occasion on which this has been done); (2) pregnancy following its removal and injections of antuitrin S (there is of course no proof of cause and effect) and (3) the very rapid recovery by a primipara of 36 with only moderate muscular development from the birth of a 9¾ lb baby involving twelve hours of strong and frequent pains after premature rupture of membranes While admitting the unwisdom of generalising from the particular one is tempted to attribute (3) to the very effective analgesia available and suggest that the wearing effect of long drawn-out severe pain in unrelieved labour plays a large part in the exhaustion which too often follows If there is any truth in this the relief of that pain becomes not a sentimental gesture undertaken from humanitarian motives but a duty incumbent on all of us who are engaged in the effort to reduce maternal mortality and industrial disability

I am indebted for permission to publish details of this case, to Mr L C Rivett, who conducted it throughout I enclose my card, but the patient being my wife, ask you to suppress my name

I am Sir yours faithfully

HORMONE TREATMENT OF UNDESCENDED TESTIS

To the Editor of THE LANCET

SIR—We read with interest in your issue of Feb 27th the article by Mr Mimpriss on the hormone treatment of undescended testes and on the whole agree with the views expressed in the letter from Drs Bishop and Hampson who very adequately summarised the present position of this form of treatment in the following week

In our last 90 cases we have seen only 2 in whom genital hypertrophy became marked in the majority there was growth of the testes which was often desirable and in less than half there was increase in the size of the penis insufficient to cause any anxiety We notice that the only patient of Mr Mimpriss's series in whom there was gross hypertrophy was six years old which we consider too young for hormone treatment We are unable to agree with his conclusion that treatment with gonadotropic hormones should be used only in bilateral cases with *subnormal genital development* since we have had numerous successes in patients with unilateral maldescent and normally developed genitalia; and we should like to assure him that we have taken special care to identify the *undescended* and the *retractile* testis In our experience hormone treatment is more likely to produce descent of the testes than pathological genital hypertrophy We feel that his lack of success in causing descent of the testes may be partly explained by the short period of treatment in most of his patients and by the fact that some patients received injections only once a week We consider that twice a week should be the *minimum*.

In our opinion Drs Bishop and Hampson go too far in stating that as the result of continuous administration of gonadotropic extracts antigonadotropic factors are elaborated in the patient's blood stream which may affect the testis adversely since as yet there is no evidence that this occurs in man We are Sir yours faithfully

A SPANISH AMBULANCE

To the Editor of THE LANCET

SIR,—Since the *fall of Malaga* the plight of the wounded and the refugees in southern Spain is very serious. My husband has taken a British University Ambulance Unit to Almeria and has succeeded in establishing a hospital two front casualty clearing stations a food station and children's clinic outside the town on the road to Lorca He hopes to establish several more at intervals of twenty miles to the point where the railway begins to run again The unit at present consists of Sir George Young Miss Thurstan (the commandant) two nurses, three drivers and two cars and an ambulance A doctor and two more nurses went out last week. There has been a wide response to appeals for supplies for the unit but its work is severely hampered for lack of surgeons

If any fully qualified surgeons were able and willing to go out it is certain that many more lives could be saved Expenses out and back will be paid and keep out there If such there are I should be most grateful if they would get in touch with me in the first place stating for how long they would be able to stay out I am Sir yours faithfully

PUBLIC HEALTH

Another Circular on the Public Health Act

In a circular (No 1576) issued last November[1] the Minister of Health encouraged local authorities to study the huge consolidating Act passed in June A second circular just issued (No 1597, 2*d*) deals with Parts V, VI, and VII of the Act which directly affect the professional duties of medical officers of health. The repeal in their entirety of the Isolation Hospitals Acts of 1893 and 1901 will be specially welcome, for the boards and committees of these hospitals had become in some districts an obstacle to progress The most satisfactory of them all, the Metropolitan Asylums Board, has already connived at its own demise, less efficient boards elsewhere have elected to remain in office They are now to be abolished, their powers being transferred to committees of the county councils which can hardly obstruct the policy of their own medical officers The Infectious Diseases Notification Act of 1889 is also repealed and the new Act gives one definition of "notifiable disease" instead of three, although even now it has its drawbacks Notifiable diseases under the new Act are those of the old list of 1889, excluding puerperal fever and continued fever Plague was not in the original list but was made notifiable later under the Notification Act That Act being repealed plague ceases to be notifiable in England and Wales after next Oct 1st unless some special order is made in the meanwhile Pneumonia (primary and secondary), dysentery, poliomyelitis, polio encephalitis, encephalitis lethargica, puerperal fever, puerperal pyrexia, ophthalmia neonatorum, and tuberculosis remain notifiable under various unrepealed Acts and orders But they do not fall within the definition of notifiable disease The lost opportunity of simplifying the notification of infectious diseases and making it of real value in modern epidemiological practice is a bitter disappointment to many medical officers The new Act gives the medical officer no new powers, and so far as clinicians are concerned the notification of disease and the procedures of hospitalisation, isolation, disinfection, and control remain substantially as they were But apart from what directly concerns medicine the Act of 1936 is a great improvement on the old complex legislation Experienced medical officers will have to discard much that has become second nature with them and to learn a new code of procedure, which is full of slight alterations But to teachers of hygiene and to D P H students the new Act should bring untold relief, for, with the rest of the codification which has been promised, it should make the learning of such law as is required by practising health officers a comparatively simple business The present circular mentions every important variation from existing law Where the circular is silent, the new law is the same as the old, or differs from it only in unimportant particulars To administrative officers, the Ministry's circulars are more important than the text of the Act itself

A Hospital Closed for Streptococcal Infection

Dr R CAMPBELL COOKE writes "Owing to the rather highly coloured articles in the daily press about the closing of the Petersfield Hospital owing to infection, it might be of interest to readers to know more details

"Petersfield Hospital has 40 beds, a nursing staff of 10, and a domestic staff of 4 On Dec 11th, 1936, a patient was admitted to a private ward with an acute nasal infection, a swabbing of the nose being returned as staphylococcal, three or four days later she developed two supra orbital abscesses and an abscess in the head of the humerus, and from all three a hæmolytic streptococcus was grown On Dec 26th a sister developed a quinsy from which the hæmolytic streptococcus was grown. Two clean operations of Jan 4th, 1937, broke down on Jan 8th and 10th respectively, and the hæmolytic streptococcus was grown from their wounds

"On Jan 18th all the staff were swabbed and reported to be negative On Feb 4th and 5th the cook and kitchen maid reported throats which were swabbed and returned as positive to hæmolytic streptococcus The staff was reswabbed and 7 of them returned as positive There was no alternative but to close the hospital The Ministry of Health were consulted and they volunteered to type the cases All staff and patients were reswabbed and 8 of these were positive, but the results of serological tests showed that 4 (2 patients and 2 staff, the nurse who had had quinsy and a healthy probationer) were of the same type, 2 (domestics) were carrying a well known epidemic type, and 2 (staff) a group that could be ignored, as it did not belong to Group A

"The hospital has been thoroughly disinfected and will reopen on March 8th"

Facing the Diphtheria Problem

The village of Markfield in Leicestershire has suffered continued recurrences of diphtheria of the grave type which is now prevalent Everything possible has been done to check the spread of the disease By "everything" is meant the sanitary routine and ritual which in the past, when dealing with the less virulent type of diphtheria, sometimes marked time with the natural course of epidemics and ended coincidently with them But Markfield has had no luck and diphtheria continues, much to the chagrin of the medical officer, Dr T W Gordon Kelly, and of the other doctors of the town, who fear, with reason, that the disease will not die out naturally until it has taken its full toll of child life Dr Kelly and his colleagues decided to urge immunisation, and for this purpose a public meeting was held by Mr. J T Jacques, chairman of Market Bosworth rural district council, at which several doctors, the clerk of the council, and other influential persons pleaded with the parents of the district to have their children immunised The *Leicester Mercury* ends its report of the meeting with the following sentence —

> "Before the meeting closed the district nurse announced that she had obtained signatures for 50 children to be treated Several parents signed forms in the room, and others took forms away"

There is agreement that diphtheria can be stemmed by immunisation, which alone of all measures is reliable to keep the disease at its lowest level Experience on a truly vast scale has proved that the incidence of diphtheria, normally one tenth of the birth rate can be reduced nine tenths, and fatality, which is about 10 per cent, abolished Slowly but surely the peoples of the world are accepting diphtheria immunisation, for we have not made the mistake of trying to enforce it, but allowed it to advance on its own merit In most parts of the country there are no real difficulties, nor obstructions to diphtheria immunisation campaigns though, human nature being what it is, it is always easier to get going during a severe epidemic which theoretically is the least favourable time to start Leicestershire however is a difficult field because of its pronounced anti vaccination attitude for the opponents of vaccination are not nice in their discriminations and carry their opposition to all forms of biological therapy The people will not be interested in the fundamental distinction between vaccination by attenuated virus and immunisation by detoxicated antigen but do *appreciate the difference between the bad arm—the* obvious disease —which follows Jennerian vaccination and the silent invisible immunity which follows the injection of antigen

---

[1] *Lancet*, 1936, 2, 1168

A condition of success is that there shall be no deception; above all, it must be explained clearly that immunity takes a long time to develop and that inoculation started during an epidemic will not give immediate safety though it is safe to promise that it will reduce the chance of death from diphtheria even if the immunity has not had time to be fully established. Though no question remains of immunisation being at least 90 per cent successful in giving individual protection we are still in the dark as to what percentage of immunes in a population is necessary to prevent epidemic prevalence arising or doing what Markfield wants at present to bring to an end a nagging prevalence which generally is *due to an intermitting carrier* Dr Kelly and the other doctors at Markfield suggested not less than 50 per cent but we do not know for there are many factors at play which are at present ill understood. The objection to immunisation that it increases the carrier rate may be without foundation but we are at present ignorant of the relationship of host immunity to toxin with parasite capability to grow on mucous surfaces

OBITUARY

CHARLES STANSER BOWKER L.R C P, L.R C S Edin

Dr Charles Stanser Bowker who died on Feb 20th last was one of the oldest medical practitioners in Monmouthshire having been in practice at Pontnewydd for more than 40 years He received his medical education at the London Hospital and the Glasgow Royal Infirmary and qualified in 1887 as L.R.C.P L R C S Edin. and L R F.P S Glasg He held resident appointments at the Glasgow Infirmary and was also a house surgeon to the Newport and County Infirmary and the Rotherham Hospital. He went into practice at Pontnewydd nearly 40 years ago and held local appointments as medical officer among others that of medical officer to the Post Office and also medical referee to several assurance companies

Although 50 years of age at the outbreak of the war he joined up immediately and with the rank of captain was in turn in charge of the internment camp at Beachley Chepstow and the embarkation camp at Southampton. At the time of his death he was director of the Royal Gwent Hospital, Newport.

WILLIAM DENISON WIGGINS M.R C S Eng D.P.H

We owe the following to a friend and colleague of the late Dr Wiggins: Dr Denison Wiggins s death at St Alphege s Hospital Greenwich on Feb 26th at the early age of 63 will come as a shock to his many friends in South London He had turned his attention mainly to surgery was a sound operator and his services were in much request in the district outside the hospital. Born in 1873 at Watlington he was educated at Magdalen College School Oxford and St Mary s Hospital He entered the poor law medical service at once and after a year at the Fulham Infirmary became assistant medical officer at Greenwich rising to be medical superintendent a position he held for 25 years As soon as he was appointed he began agitating for better surgical quarters and by great persistence got them so much improved that when the L.C C took over it was recognised at once as a surgical centre and to his intense delight good modern theatres were installed and electrical and light treatment provided for the after-care of orthopædic and other cases At an early date he organised the nursing school on modern lines and will be long remembered for his extremely practical lectures to the nurses. Here again he saw his ambitions realised when during the last few years one of the finest and most modern nurses homes in London was completed. In 1904 he published a book on midwifery for nurses and gave many refresher courses for practising midwives He reported clinical cases occasionally in the medical press and had always an interesting case or cases to discuss with any medical colleague who came in He was rather better than most people at any sport that he took up A golfer of outstanding merit, he was a member of the old Blackheath Golf Club He was a first rate shot a good tennis player and later when his health began to fail he became rather above the average at croquet A keen pigeon fancier he raced his birds as far as the North of Scotland He played an excellent hand at bridge A regular attendant at masonic meetings he had held office as grand master of his lodge Along with all these interests went an insatiable taste for curios of all sorts There was hardly a thing in his house that had not some exciting history behind it, and his collection of china and old furniture was extensive He married Marie Julie Breting of Geneva who predeceased him and leaves a son who is a student at Guy's Hospital and one daughter

ROBERT LACHLAN PINKERTON, M.D Glasg J P

The death on Feb 23rd of Dr Robert Pinkerton of Norwood removes from the Streatham district a prominent practitioner who also worked actively on behalf of municipal interests in the locality Born at Paisley he received his medical training at Glasgow University and graduated M.B C.M. in 1888 proceeding with a short interval to the M D degree He held appointments at the City of London Hospital for Diseases of the Chest and started practice in Harlesden but having been resident medical officer of the Surrey Dispensary he came to South Norwood where he *rapidly* achieved professional success. He was appointed police surgeon to the South Norwood section a position which he filled for over thirty years He was honorary medical referee to the Streatham Home and Hospital for Incurables had been chairman of the Croydon Medical Association and also an active member of the executive committee of the Croydon division of the B M.A During the war he was civil medical officer to the Croydon War Hospital at Norbury while his public activities gained him a position as justice of the peace on the Croydon Borough Bench Here he proved an acquisition, for he was regularly present at the Wednesday morning courts and devoted much time and thought to the exercise of his duties He was a trustee of the Stanley Technical Trade School, and held the position of chairman of the board for sixteen years until his death This occurred suddenly at his home at South Norwood Hill, from a heart attack, but he was carrying out his professional duties to the end. He was 71 years of age

JOSEPH CLOUGH, M R C S Eng

Dr Joseph Clough, who died last week at Moortown, Leeds, had practised in the Hunslet district for over forty years He was born at Cleckheaton and received his medical education at the Leeds Medical School After a period of service at the Bolton Infirmary, he became house physician at the Leeds General Infirmary, being later appointed anæsthetist and assistant pathologist He was a well equipped physician, and contributed occasionally to these columns

FREDERIC WILSON STANSFIELD,
M D Manch , D P H , F L S

We regret to record the death of Dr Frederic Stansfield, for many years a leading practitioner in Reading, where his death occurred on Feb 28th He was born at Todmorden, the son of Abraham Stansfield, a well known botanist and nurseryman, and for a time was himself in business as a fern cultivator, but deciding on the medical profession he entered the medical school of Victoria University, Manchester, with an exhibition in physiology He graduated as M B , Ch B in 1889, proceeding at the shortest interval to the M.D degree, and in 1893 he obtained the diploma of D P H at Cambridge In that year he went into practice at Reading and came to hold a prominent position in the profession, being elected president of the Reading Pathological Society and of the Reading and Oxford branch of the B M.A He maintained his hereditary and early interest in ferns, contributed papers on the filices to the *Proceedings* of the Linnean Society, of which body he was a fellow, and for a time edited the *British Fern Gazette* He was in his 83rd year at the time of his death, and had been a widower some years , his son, Dr T Stansfield, practises in Reading

RICHARD CRESSWELL, M R C S Eng , D P H

Dr Richard Cresswell, who died early this month in a nursing home at Bath, was a very senior member of the medical profession, for he qualified 70 years ago as M R C S Eng , being also one of the earliest to take the diploma of D P H Lond. He held an appointment as a young man at the London Lock Hospital and for a time was in the Colonial Medical Service, being stationed at St Helena He then went into practice at Cheltenham where he was for a period medical officer of health to the urban district council Later he practised in Portishead for some thirty years He was 93 years old at the time of his death

CHARLES WILFRED COGHLAN, L.R C P ,
L R C S Edin

The death occurred recently at Longton of Dr Charles Coghlan, a member of a well known Longton family of doctors He received his early education at Ratcliffe College, Leicester, went for his professional training to Edinburgh, and qualified in 1902 as L R C P , L R C S Edin and L R F P S Glasg He went into medical practice in York but joined up at the outbreak of war and saw much service in the Near East as an officer in the R A M C Soldiering was not new to him for he had served for three years in the Royal Scots Volunteers Unfortunately he contracted malaria and after the cessation of hostilities he retired from practice for a time and travelled much abroad, but later on the death of his brother he returned to carry on the practice But he was practically an invalid for the rest of his life He had an extraordinary medical pedigree, being one of seven brothers, of whom one died in infancy, but the other six all entered the medical profession

PARLIAMENTARY INTELLIGENCE

CRITICISM OF PRISON CONDITIONS

In the House of Lords on March 3rd the Earl of Kinnoull drew the attention of the Government to the conditions obtaining in H M prisons and asked whether the idea of imprisonment to-day was partly one of revenge against the person who had broken the social code, or one of the reform of the prisoner He had recently read a book called " Walls Have Mouths," by Mr Macartney, who was an ex convict The author described his experiences in Wandsworth Prison before he was sent to Parkhurst convict establishment While he was at Wandsworth a man was hanged and Mr Macartney said that one could hear the noise of the drop all over the prison If that was so (said Lord Kinnoull) surely it was barbarous Mr Macartney also said that at Parkhurst in the strong cells there were no windows or heating and men occasionally put in a winter without a blanket, and mostly with only a shirt on Lord Kinnoull did not think that in the winter one would treat an animal in that way Another thing that struck him in reading the book was the unnecessary amount of duplication that went on as one passed from one prison to another The prisoner came before the medical officer and had to give his whole medical history over and over again, although it was all written down on a form in front of the medical officer He could well understand that the unnecessary amount of nagging by warders drove a person nearly insane after any length of time in prison Medical men said that monotony of diet over a long time was deleterious to health In Macartney's book it was stated that the prison doctors at Parkhurst found it necessary to put convicts in hospital for a fortnight—every two years, he thought—and give them hospital diet in order to get away from the routine which they underwent He thought that the food might be varied a little Apparently convicts were flogged with a cat-o' nine tails in all cases of an assault on a warder , that seemed unnecessary brutality When a man lost his reason for a moment no amount of fear of flogging would stop him Macartney quoted cases of men who had been flogged several times, but this had not deterred them, but had made them more like brute beasts He took the view that nearly all people who were convicts had a mental kink, and he thought that at any rate 90 per cent of them would be far better treated by psychologists than by prison treatment He found that where people had been sent in for observation because their behaviour was somewhat peculiar they had been kept in the observation landing for years until they had been let out and when let out they had been promptly discharged to the county asylum It seemed to him utterly stupid, when quite clearly it must have been known over a number of years whether a person was mentally deficient to keep him under a sentence and then discharge him to a mental asylum. There was surely a great need for reform there

DENIAL OF ALLEGATIONS

The Marquess of DUFFERIN AND AVA said he had never heard a speech containing so many allegations based on one book by one person—and that an ex convict—without any attempt whatever to produce evidence from outside sources The assaults on the officers at Parkhurst in 1928 1020 and 1930 were confined to two three and nine cases respectively He said he would take the responsibility of telling Lord Kinnoull that the story of hearing the drop fall was pure nonsense and complete imagination. It was not possible to hear the drop fall at Wandsworth In 1910 the prison population of this country was just under 21 000 at the present moment it was only 10 000 Of all the persons recently received into prison for the first time for serious offences during the years 1030–33 80·7 per cent so far as was known had not returned to prison a second time up to the end of 1035 Therefore it did seem that reforms had been made even if Lord Kinnoull thought that they had not gone far enough in the direction of keeping people out of prison and preventing people who had been in prison from being forced back into criminal life Solitary confinement had been practically done away with Every prisoner now unless there was some medical reason worked from the very beginning in association with other prisoners But contamination might easily follow if all sorts of prisoners were allowed to mix freely together Therefore the object of their reforms had always been to classify prisoners as clearly and as definitely as was within their power The first and obvious classification had been the institution of Borstal which had at one stroke taken one-sixth of the prison population and put them into places where they could not be contaminated by older and more vicious criminals It was obviously very difficult to have a system of classification within the prison itself It had been the policy of the Commissioners to reserve certain establishments for certain classes of prisoners Furthermore the Commissioners had developed the very right policy of collecting as far as possible young prisoners between 10 and 21 who were serving very short sentences But however hard they tried they could not in these collecting centres give the same training as they gave in a Borstal institution. The Commissioners had frequently drawn attention to the fact that magistrates and others who had to administer the law should think again and again before they sent young people to prison particularly those who had not previously been guilty of offences In 1935 of the boys sentenced to imprisonment 38 per cent had not previously been convicted of an offence and it was the firm conviction of the Commissioners and of the Government that in many of those cases probation would have met the case far better and that in the remainder of the cases a longer term of Borstal imprisonment would have done the boy far more good The only consolation was that whereas in 1032 a total of 2653 boys were sentenced to imprisonment the number had fallen to 1608 in 1035 It was the firm policy of the Commissioners at the moment to reduce to a minimum the period during which prisoners were locked in their cells Since 1031 it had been possible very greatly to increase the staff of prison officers available to look after the prisoners The spirit of prison reform was very much alive at present The Commissioners were doing everything in their power to fit these people for the new life they would have to take up when they came out The Commissioners were fully aware of the importance of the selection of suitable warders The nagging which had been referred to no longer existed and the present type of warder was quite different from the type upon which Mr Macartney drew for his imaginary pictures But he would not like Lord Kinnoull to think that either the Government or the Commissioners were complacent They were fully aware that there was still much that could be done —The Earl of KINNOULL said that he was very pleased that some of the allegations of Mr Macartney had now been denied, because they had never been officially denied before He was very gratified to hear that reforms were taking place and that more reforms were in contemplation

NOTES ON CURRENT TOPICS

The Factories Bill in Committee

The Factories Bill was further considered by a standing committee of the House of Commons on March 2nd and 4th

CUBIC SPACE AND OVERCROWDING

On Clause 2 Mr ELLIS SMITH moved that the proviso in the Bill that for five years the figure should be 250 cubic feet and should afterwards continue at the lower figure where a workroom had effective mechanical ventilation should not apply when overtime was being worked He said that many of the factory inspectors had very large areas and it might be years before they got round to inspect all the premises in their area Employers should not be allowed to work people overtime in crowded conditions The standards they were aiming at setting up under the Bill should be national standards and young people should not be called upon to work overtime in conditions which did not conform with those standards.—Sir J SIMON said there was a practical difficulty in making one rule regarding overcrowding in a workroom during the period before overtime began and a different rule when overtime began He was not satisfied with the form of the proviso in the Bill and it should be modified (cheers) He did not like it in so far as it made possible an indefinite prolongation of the less satisfactory standard of cubic space They did not intend to allow the proviso to operate for ever —Sir J HASLAM agreed that they did not want slum factories to be perpetuated for ever at a time when they were abolishing slum houses They should be thoughtful and cautious but bold in regard to factory legislation —The amendment was withdrawn

Sir J SIMON moved an amendment to restrict the reference to five years in the proviso to factories which had been continuously in the same occupation since the date of the passing of the Bill into law —The amendment was agreed to

Sir J SIMON moved a further amendment to alter part of the proviso and provide among other things that where effective and suitable mechanical ventilation was not provided the proviso should not continue to apply although the five years period had not expired —The amendment was agreed to

REASONABLE TEMPERATURE

On Clause 9 (which provides that effective provision shall be made for maintaining a reasonable temperature in each workroom but there shall be no escape into the air of fumes likely to be injurious or offensive) Mr BUCHANAN moved an amendment to delete the word reasonable and insert a provision that the temperature should be within the limits of 00 –05 F He urged that the question of what was a reasonable temperature in a workroom should not be left to the employer —Sir J SIMON said that the amendment was not a practical proposal They could not have a cast iron rule to deal with the wide varieties of work carried on in different factories The Secretary of State was given power by a subclause to make regulations with regard to temperature in any particular class of work.—The amendment was withdrawn

Miss HORSBRUGH moved an amendment to provide that the word reasonable should be qualified by the provision having regard to the purposes for which the premises are used —Sir J SIMON said that in interpreting the word reasonable the question of the purposes for which premises were used was a factor to be taken into consideration but it was not the only one The amendment would tend to exclude the consideration of whether the temperature was reasonable for the workpeople —The amendment was withdrawn

Mr **GRAHAM WHITE** moved an amendment to provide that there should be no escape into the air of fumes likely to affect the purity of the air It was, he said, important that the air in a workshop should not be contaminated There might be gases which were dangerous but not offensive —Mr **LLOYD** said that the amendment was very similar to an existing provision in the law The fundamental question was not the purity of the air, but whether there was anything in the air which was injurious or offensive to an individual —The amendment was withdrawn

Mr **MANDER** moved an amendment to delete the words "is done sitting" in a subclause which provided that in workrooms in which a substantial proportion of the work was done sitting, and did not involve serious physical effort, a temperature of less than 60° F should not be deemed, after the first hour, to be a reasonable temperature He said that the phrase "is done sitting" might be a temptation to a few employers not to provide seats —Mr **LLOYD** said the amendment would make the scope of the subsection vague and difficult to enforce If a gross case of an attempt to avoid the provisions of the Bill came to the attention of the Home Office they would consider prescribing a standard of temperature in that particular class of work.—After further debate, Sir J **SIMON** said he would have the matter further considered, and the amendment was withdrawn

"ADEQUATE VENTILATION"

On Clause 4 (which provides that there shall be effective provisions for securing that a workroom is adequately ventilated and for rendering harmless, so far as practicable, fumes, dust, and other impurities that may be injurious generated in the course of work) Mr **BUCHANAN** moved the deletion of the words "so far as practicable"—Mr **LLOYD** said it would not be right to make an employer criminally liable when he had done all that was practicable in the circumstances —The amendment was withdrawn

Mr **SILVERMAN** moved an amendment to add a provision that no mechanical ventilation should be deemed efficient which did not secure such frequency of complete changes of air in a workroom as the Home Secretary might direct —Sir J **SIMON** said that the whole science of ventilation was developing rapidly The most important inquiries of a practical and scientific kind were going on He thought it was undesirable to put in a Statute, which might last for many years, what amounted to a limiting provision —Sir E **GRAHAM-LITTLE** said he did not think that attention had been sufficiently given to the importance of changes of the air in the room. It was not a practical proposition to insist on so many changes an hour There was a far better system that could be adopted, and he regretted that he had not been allowed to move his amendment to provide for testing the ventilation and coolness of the air He hoped that the Secretary of State would consider the adoption of approved methods used extensively in most progressive Government Departments, including the Home Office and the India Office, to test the efficiency of the ventilation and the temperature of the air It was a simple scientific instrument in the form of a thermometer, and its value had been tested —After further discussion the amendment was withdrawn

"SUITABLE LIGHTING"

On Clause 5 (which provides that effective provision shall be made for maintaining suitable lighting, natural or artificial, in every part of a factory in which persons are working or passing), Mr **CARTLAND** moved an amendment to provide that the Home Secretary might by special regulations direct that any operation in a factory should be carried on, where sufficient natural lighting was available, during the day time He said it was desirable to deal with those processes which it was undesirable to carry on by artificial lighting There were industrial processes, such as putting decorations on chocolates for example, which were done by hand and were of a very detailed character If people did work of that kind by artificial light it strained their eyesight to such an extent that they might be in danger of eventually going blind.—Mr **HAMILTON KERR**, who supported the amendment, said that the Institute of Industrial Psychology had carried out exhaustive researches into the question of lighting in factories and they had amply proved the bad effect that poor lighting had on the health and productive capacity of workers The object of this amendment was to ensure in factories that wherever possible natural lighting should be preferred even to the best artificial lighting —Sir J **SIMON** said that he did not think it was a practical matter to carry out this amendment If it was generally understood that there would be better work, more production, and more accurate work in many trades when the work was done in daylight than would be the case if the employer went to the expense of installing artificial lighting, then he thought they would encourage people to do the work in daylight But he would not envy the Home Secretary, whoever he might be, if he had to draw up regulations under this particular amendment The Committee would appreciate that they were taking a great step forward in Clause 5—the first real step forward in this Bill There was not in the factory law at present any provision requiring adequate lighting, except in certain dangerous trades They were doing a pretty big thing in Clause 5 and they ought not to complicate it unnecessarily —The amendment was withdrawn

Mr **RIDLEY** moved an amendment to delete the proviso that nothing in the clause, or in any regulations made under it, should be construed as enabling directions to be prescribed as to whether any artificial lighting is to be produced by electricity, gas, or any other particular means He said that he thought the Home Secretary should be in a position to prescribe the precise form of lighting which seemed to be desirable and imperative in order that a sufficient and suitable standard of lighting might be employed —Sir J **SIMON** said he did not wish to use the Factories Bill as an occasion for an argument about the efficiency of different kinds of lighting It was no part of the business of the Home Office to say how the lighting was to be produced What they were concerned with was sufficient and suitable light, and not with how the light was produced —Mr **BROAD** said that for most industrial processes where fine work and steadiness of hand were required gas lighting was obsolete If it was necessary for the safety of the worker to put in electric light the Secretary of State would not be able to prescribe it The Bill prescribed cubic capacity Electric light was the only light which would give the power without combustion taking place at the point of illumination, and if they were to have gas light they ought to double the amount of cubic air space, because gas would consume more air than the workers were breathing —Sir J **SIMON** suggested that they should leave out these two extremely provocative words—electricity and gas—and that the words should run "as to whether any artificial lighting is to be produced from any particular source of illumination"—Mr Ridley's amendment was withdrawn and the amendment suggested by the Home Secretary was agreed to

In the House of Commons on March 5th the Prohibition of Vivisection on Dogs (Scotland) Bill came on for second reading one minute before 4 o'clock, when the debate was automatically adjourned

In the House of Lords on March 3rd Viscount **GAGE** presented a Bill to amend the law with respect to the discharge of trade effluents into public sewers of local authorities

The Bill was read a first time

QUESTION TIME

WEDNESDAY MARCH 3RD

Humidity in Great Britain

Mr Markham asked the Under Secretary of State for Air when it was hoped to have published maps showing relative humidity in Great Britain and whether it was intended to accompany such maps with a new handbook of normals —Sir P Sassoon replied It is estimated that the necessary computations will be completed in about nine months' time and that the maps will be published within 12 months The average values will be published in a book which will contain maps showing the geographical distribution of relative humidity for each month and for the year as a whole

THURSDAY MARCH 4TH

Public Kitchens in Necessitous Areas

Mr Wilson asked the Minister of Labour whether in view of the popularity which had attended the establishment of milk bars he would consider the possibility of setting up in some of the more necessitous areas public kitchens where at a small cost the more nutritious kinds of food could be supplied either for consumption on the premises or otherwise —Mr Ernest Brown replied The service which the hon Member suggests should be established does not lie within my powers as Minister of Labour

Viscountess Astor With whom do the powers lie ?

No further answer was given.

Meals at Juvenile Instruction Centres

Mr George Hall asked the Minister of Labour whether the National Advisory Council for Juvenile Employment had made any recommendation with regard to the provision of meals at juvenile instruction centres and whether in view of the need for improving national physique the Minister proposed to take steps to provide meals for these juveniles.—Mr Ernest Brown replied : I received a few days ago an interim report on this matter from the National Advisory Council for England and Wales, and am expecting very shortly a report from the Council for Scotland The recommendations made will be considered at once and a decision taken as soon as possible

Mr Hall Will the report be published ?

Mr Brown : I hope to make it available as soon as I have considered it

Women and Young Persons in Textile Factories : the Two shift System and Overtime

Mr Riley asked the Home Secretary how many textile factories if any in the West Riding of Yorkshire were working a two-shift system and how many women and young persons were employed on a two-shift system in such factories —Sir John Simon replied The number of textile factories in the West Riding in which women and young persons over 16 are employed on a two-shift system is 10 and the number of women and young persons so employed is rather over a thousand

Mr Riley asked the Home Secretary in how many textile factories in the West Riding of Yorkshire women and young persons had been employed on overtime beyond 48 hours in any one week and the approximate number of overtime hours so worked per week for the year ending Dec 31st 1936 —Sir John Simon replied : I regret that the statistics for which the hon Member asks are not available but I am informed that a considerable amount of overtime beyond 48 hours was worked last year by women and young persons in the textile factories in the West Riding

Government and Air raid Precautions

Mr Jenkins asked the Home Secretary whether in view of the differing opinions and the public concern as to the effectiveness of the air raid precautions now in course of preparation he would undertake to submit all the information to an impartial group of competent persons for examination and report —Mr Geoffrey Lloyd replied : In devising measures of air-raid precautions the Government avails itself of the best advice available and my right hon friend sees no reason for an inquiry of the kind proposed by the hon Member

Mr Jenkins : Is the hon gentleman aware that a meeting was held in a committee room of this House at which a number of scientists from Cambridge University met a large number of Members of all political parties as a result of which grave suspicion has been created in their minds that the Government s provisions up to date are not adequate ; and will he take steps to see that the public are given proper assurances that the provisions are the best that can be obtained ?

Mr Lloyd : Perhaps the hon Member has not followed the answers which I have given recently pointing out that the experiments by these Cambridge scientists are open to very grave objection and are not considered to be of practical value

Miss Wilkinson If there is some dispute and if they question the Government s tests and the Government question their tests, why do the Government refuse to send the matter to some impartial expert body ?

Mr Lloyd : Those scientists can be said in general not to have had great experience in this particular technical work, while the Government are advised by many of the principal professors amounting to nearly 100 of various universities, as well as other experts including those of the chemical industries who have had the greatest experience in the country in this work.

Mr Jenkins : Is the hon. gentleman aware that at the meeting to which I have referred a letter was read from one of the most highly qualified and most experienced scientists in this country expressing the view that the provisions are totally inadequate and should be inquired into carefully ?

Mr Lloyd : I should be very glad to have that letter

Air raid Wardens

Mr Baxter asked the Home Secretary if he was now in a position to make any further statement regarding the organisation of air raid wardens —Mr Geoffrey Lloyd replied : Yes Sir A memorandum is being dispatched to-day to borough and district councils recommending them to organise in consultation with the police a service of air raid wardens to supplement the normal resources of the civil authorities for safeguarding the general public in the event of air attack. It is proposed that fixed posts should be established from which the wardens should operate Each post will be responsible for a particular area and it is recommended that the division of towns into suitable areas should be started at once In residential districts posts should be allotted approximately on the basis of one post to every five hundred inhabitants while in business areas the distribution of posts would be governed rather by distance—for instance a post every quarter of a mile might be found suitable The minimum number of wardens required would be two per post It is intended that the wardens should be in a position to advise their fellow citizens on the recommended precautions and should be available to give immediate assistance in dealing with air raid damage The wardens would probably also be used in connexion with the distribution of civilian respirators. These services would be performed in the neighbourhood of the warden s home or place of business Volunteers who undertake these responsibilities will be given the training required and will be supplied by the Government with such equipment as is considered necessary to enable them to carry out their duties effectively This organisation will constitute an essential supplement to the local authorities air raid precautions services and the Government are confident that a sufficient number of volunteers will be forthcoming for the effective performance of this very important part of the work of civil defence The memorandum is being placed on sale and copies are being placed in the library of the House

Compulsory Pasteurisation of Milk

Mr Robert Morrison asked the Minister of Health whether in view of the evidence contained in the annual report of the chief medical officer of his department for 1935 of serious outbreaks of scarlet fever solely due to the sale of raw milk, he intended to introduce legislation during the present session providing for the compulsory pasteurisation of all milk —Sir KINGSLEY WOOD replied I am not in a position to add anything to the reply given to the hon Member on Nov 12th last

Mr MORRISON Does the right hon gentleman realise the dangers of this situation, and does he contemplate legislation ?

Sir K WOOD I cannot contemplate legislation at the present time

Workers' Hours

Mr WILSON asked the Minister of Labour the numbers of insured persons whose ordinary hours of work per week were over 48, 44 to 48, 40 to 43, and under 40 —Mr ERNEST BROWN replied For certain groups of industries (textiles, clothing, treatment of non metalliferous mine and quarry products, and the brick pottery, glass, and chemical industries) statistics showing the proportions of workpeople, employed by firms who supplied information in response to an inquiry made by my department, whose normal weekly hours, in October, 1935, were less than 44, 44, 44¼ to 46¾, 47, 47¼ to 47¾, 48, and over 48 respectively, are published on page 48 of the *Ministry of Labour Gazette* for February, 1937 Corresponding statistics for other manufacturing industries, and for certain non manufacturing industries, are now in preparation and will be published in subsequent issues of the *Gazette* The particulars given relate to wage-earners, similar figures for insured salary earners are not available

MONDAY, MARCH 8TH

Typhoid Outbreak in Liverpool

Mr GROVES asked the Minister of Health whether any investigation had been made into the milk consumed by the sufferers in the recent outbreak of typhoid at Liverpool, and whether the majority obtained their milk from the same source or from different sources —Sir KINGSLEY WOOD replied This outbreak has been investigated by officers of the Liverpool City Council, and I am informed that some 60 per cent of the persons affected obtained their milk-supply from the same retailer But there is no reason to think that milk was the source of infection in these cases

Blind Persons and the Poor Law

Miss WARD asked the Minister of Health whether he could announce the introduction of the Bill to extend the principle of removal of the blind from the administration of the poor law, as foreshadowed in his speech at Worcester last September —Mr HUDSON, Parliamentary Secretary to the Ministry of Health, replied This Bill is in course of preparation, but my right hon friend is not yet in a position to announce the date of its introduction

M P 's and Facilities for Physical Exercise

Sir REGINALD CLARRY asked the Parliamentary Secretary to the Ministry of Health, as representing the First Commissioner of Works whether he would consider the possibility of setting aside a room and facilities in the House of Commons to enable Members during their hours of attendance to take requisite exercise in conformity with the general desire for a keep fit campaign —Mr R S HUDSON replied My noble friend has considered the matter in consultation with the authorities of this House He has much sympathy with the request of my hon friend, but regrets that the demand on the accommodation for the purposes of public business is so great that it is not possible to accede to it

Ministry of Labour versus a Manchester Hospital

Mr ECKERSLEY asked the Parliamentary Secretary to the Ministry of Health as representing the First Commissioner of Works, whether, before the plans for the new labour exchange in Manchester were approved full consideration would be given to the value to the city of the Robey street branch of the Manchester Royal Infirmary and to the necessity for ensuring that the new exchange would not interfere with its light or amenities

Mr CARY asked the Minister of Labour whether his attention had been called to the fact that the new labour exchange building which was being erected close to the south wall of the Manchester Royal Infirmary would rob of light and render useless the wards of this institution, and whether, in view of this fact and the fact that a large sum of money had recently been spent on the infirmary he would give instructions that some other empty space or unused building in the district should be used for this purpose —Lieut Colonel MUIRHEAD replied I am aware of the position regarding the erection of the new central employment exchange for Manchester, and my right hon friend and the First Commissioner for Works have discussed the matter with the chairman and other members of the board of the Royal Infirmary After very careful consideration my right hon friend has decided that the building of the exchange should proceed, and the contractors are now working on the site

Demonstration of Anti Gas Respirator at Westminster

Mr ASSHETON asked the Home Secretary if he would make arrangements for the exhibition to Members in some convenient place of a respirator of the type designed to protect the civilian population —Mr GEOFFREY LLOYD, Under Secretary, Home Office, replied Yes, Sir I am arranging for a number of these respirators to be available for inspection by hon Members in the room off the Members' cloak room, during the hours while the House is sitting, on Monday, March 15th, and following days An officer will be in attendance to assist hon Members who may wish to try on the respirators and to answer any questions

TUESDAY, MARCH 9TH

Pensions for Blind Persons

Mr WESTWOOD asked the Secretary of State for Scotland if a Bill was to be introduced to reduce from 50 to 40 years the age at which pensions might be paid to blind persons —Mr ELLIOT The answer is in the affirmative

Mental Hygiene Out-patient Clinics in Scotland

Mr LEONARD asked the Secretary of State for Scotland the number of out patient clinics functioning under the Board of Control for the use of persons conscious of incipient mental trouble, and whether they were open continuously or at separate advertised periods —Mr ELLIOT replied There are nine mental hygiene out patient clinics in Scotland—four in Glasgow, three in Edinburgh, one in Paisley and one in Perth Seven are attached to general hospitals and all are under the direction of psychiatrists from mental hospitals They are open at advertised times

MEDICAL MEMBERS OF THE L C C

ALL ten medical members of the London County Council offered themselves for re election on March 4th when, outside the City of London, every seat was contested Two of the candidates were unsuccessful Dr Henry Robinson who was defeated in Kensington (North) and Dr S McClements in Woolwich (West) Dr Doris Odlum contested Hammersmith (North) without success The eight medical men and women who will serve on the Council for the next three years are

Name	*Representing*	
Dr C W Brook	Southwark (North)	Lab.
Dr S Monckton Copeman	Hampstead	M R
Dr J A Gillison	Bermondsey (Rotherhithe)	Lab
Mr Somerville Hastings	Stepney (Mile End)	Lab
Dr Bernard Homa	Hackney (Central)	Lab
Dr S W Jeger	Shoreditch	Lab
Dr F Barrie Lambert	Westminster (St George's)	M P
Miss F Rickards	Greenwich	Lab

Lab = Labour M R = Municipal Reform

The new Council held its first meeting on Wednesday when Lord Snell was re elected chairman.

MEDICAL NEWS

University of Cambridge

Dr E D Adrian F R S Foulerton professor of the Royal Society and fellow of Trinity College has been appointed to the chair of physiology in succession to Sir Joseph Barcroft who is retiring on Oct 1st

Dr Adrian who is 47 was educated at Westminster School Trinity College Cambridge and St Bartholomew's Hospital medical college He qualified in 1915 and obtained his M.D in 1919 After a period as resident medical officer at the National Hospital Queen-square he returned to Cambridge as university lecturer in physiology He was awarded the Rolleston memorial prize in 1916 and the Gedge prize in 1917 He was elected a fellow of the Royal Society in 1923 and the following year a fellow of the Royal College of Physicians of London He gave the Oliver-Sharpey lectures at the College in 1925 speaking on the interpretation of the electromyogram, and was awarded the Baly medal in 1929 In 193 jointly with Sir Charles Sherrington he received the Nobel prize in medicine and physiology and in the same year he was appointed to the Medical Research Council In 1934 he was awarded the Royal medal of the Royal Society Dr Adrian holds the honorary degrees of D.Sc. of Philadelphia and LL D of McGill. His publications include "The Basis of Sensation published in 1928 and The Mechanism of Nervous Action published in 193 His interest in clinical neurology first aroused during the late war has brought his neurophysiological studies into touch with medicine at many points

University of London

The following have been recognised as teachers in the university and assigned to the faculty of medicine

Dr B W Town (chemistry St Bartholomew's Hospital) Mr W M Collee (chemistry Guy's Hospital) Mr Constantine Lambrinudi (orthopædics Guy's Hospital), Dr Thomas Anwyl Davies (venereal diseases, St Thomas's Hospital) Mr N R Barrett (surgery St. Thomas's Hospital) Dr R K Bowes (obstetrics and gynæcology St. Thomas's Hospital) Mr W. R Bristow (orthopædics St. Thomas's Hospital), Dr G B Dowling (dermatology, St Thomas's Hospital) Mr P G Doyne (ophthalmology, St Thomas's Hospital), Dr J St C. Elkington (medicine St. Thomas's Hospital) Dr Geoffrey Fildes (radiology St. Thomas's Hospital) Dr Harold Gardiner-Hill (medicine, St. Thomas's Hospital), Dr Reginald Hilton (medicine St. Thomas's Hospital) Mr W A Mill (oto rhino laryngology St. Thomas's Hospital) Mr D F A. Neilson (oto rhino laryngology St. Thomas's Hospital) Dr G G Penman (ophthalmology St. Thomas's Hospital) Mr George Perkins (orthopædics St Thomas's Hospital) Dr J F Smith (medicine St Thomas's Hospital), Mr B W Williams (surgery, St. Thomas's Hospital) Dr H D Wilson (anæsthetics, St Thomas's Hospital) Dr A J Wrigley (obstetrics and gynæcology St Thomas's Hospital) Dr J. M. Wyatt (obstetrics and gynæcology St Thomas's Hospital) Miss C. L. T Lucas (biology, London (R F.H) School of Medicine for Women) and Mr Harold Davis (pharmacy University College Hospital)

Mr C Jennings Marshall and Mr C E Shattock have been appointed internal and external examiners in surgery in place of Mr G T Mullally and Mr Davies-Colley who have resigned Mr C W G Bryan has also been appointed a fifth examiner in surgery to be called on if required and Prof Lambert Rogers an associate examiner

The university medals in pathology psychological medicine and surgery have been awarded at the M.D and M.S examinations in December to Dr A H T Robb-Smith (St Bart's) Dr A C Dalzell (King's Coll) and Mr J B Gilchrist (Middlesex) respectively

A Carpenter medal together with a money prize will be awarded shortly for work of exceptional distinction in statistical genetic comparative or experimental psychology including the functions of the central nervous system and special senses for which a doctor's degree (other than the Ph.D) has been awarded during the last three years Application should be sent to the academic registrar not later than June 10th

A public lecture on blood groups and genetics will be given by Dr V Friedenreich of Universitetets Retsmedicinske Institut Copenhagen on Wednesday March 1 th at 5 30 P M Dr R A Fisher F R S will be in the chair The lecture will be held at the Galton laboratory University College W C and is open to the public without fee

Besredka Prize

The laboratoires La Biothérapie have founded a Besredka prize of Frs 15 000 to be offered annually for an essay in French on local immunity in its therapeutic applications The first award will be made in June 1938 and entries should be sent to the laboratories 3 rue Paul Barruel Paris XV before Dec 31st

Department of Health for Scotland

Dr J M. Mackintosh medical officer of health and school medical officer for the county of Northampton has been appointed chief medical officer of the Department of Health in succession to Dr J L Brownlie who has resigned

Dr Mackintosh who is 46 years of age was educated at Glasgow High School and Glasgow University He graduated M.A. in 1911 and M B in 1916 He served in the late war as a sergeant in the Royal Army Medical Corps as a combatant officer in the Cameron Highlanders and later in charge of a special hospital division After demobilisation he acted for a year as a medical officer to the Ministry of Pensions and in 1920 entered the local government service and was appointed assistant medical officer for Dorset. In 1923 he went to Burton-on Trent in the same capacity and was there responsible for establishing an orthopædic scheme and a combined health centre and laboratory After three years as medical officer of health for Leicestershire he took up his present position in 1930 Dr Mackintosh is a barrister-at law of Gray's Inn and is the author of reports on rural housing and water-supply He is chairman of the propaganda committee of the British Social Hygiene Council.

Physical Training in Scotland

Sir Ian Colquhoun has been appointed chairman of the national advisory council appointed to consider the best methods of meeting the needs for physical recreation in Scotland The members include the following Dr W L Burgess Prof E P Cathcart, F.R.S Lord Clydesdale M.P Mr W A Cochrane Dr G C Cossar and Colonel P S Lelean F.R.C.S Captain E D Stevenson has been appointed secretary of the council and may be addressed at 4 Great Stuart-street Edinburgh

Margaret street Hospital for Diseases of the Chest London

On Monday March 15th a clinic for the prevention and treatment of hay fever which will remain open from 10 A.M to 1 P M daily (except Saturdays and Sundays) until the end of the summer will be inaugurated at this hospital The treatment will include intranasal ionisation and further information may be had from the secretary of the hospital

Medical Society of London

At a dinner at Claridge's on March 4th celebrating the 162nd anniversary of this society the first speaker was Lord Wright the Master of the Rolls He praised medicine at the expense of law but quoted from Johnston Abraham's biography of Lettsom the remark about a doctor who always hesitated in drawing conclusions from uncertain premises and appeared to little advantage in the sick room Sir William Willcox said that the society still displayed the characteristics aimed at by Lettsom at its foundation; but its discussions steadily became more learned and critical One could learn more he thought by attending a meeting of an hour and a half than by weeks of studying books and medical journals for one got a proper perspective and truth without embellishment The financial position of the society was now better perhaps than it had ever been and nothing was lacking save an endowment fund The number of fellows exceeded 600 and the average attendance had doubled in twelve years being now 50 In conclusion Sir William announced that Dr Arnold Chaplin had just presented to the society his collection of nearly 400 engravings of medical men which he hoped might form the nucleus of an even larger collection Mr J E H Roberts dealt with The Guests comprehensively yet concisely and responses came from Lord Burghley M.P Sir Arthur MacNalty and Sir Edward Tindal Atkinson Lord Burghley after expressing his respect for doctors and income tax collectors turned to the physical state of the nation and deplored the fact that other countries—and not only the dictatorship countries—have stolen a march on us in cultivating physical fitness In all other respects British social services led the world, and what was chiefly essential at this moment was to stir the imagination of young people Sir Arthur MacNalty reviewed the relations between the Medical Society of London and preventive medicine recalling that Lettsom was interested in many of the subjects that engross public health authorities to-day The closer clinical and preventive medicine could be brought together he said the more they would achieve

Dr H J Shirley, consulting anæsthetist to University College Hospital, has been appointed a deputy lieutenant for the County of London, and Mr Charles Leonard Isaac, senior surgeon to the Swansea General Hospital, a deputy lieutenant for Glamorgan

Royal Medical Benevolent Fund

The 101st annual general meeting will be held in the library of the Medical Society of London (11, Chandos street, Cavendish square, W) on Tuesday, March 16th, at 5 P M Sir Thomas Barlow, the president, will be in the chair, and the business will comprise the reception of the annual report and statement of accounts and the election of officials and committee of management for the ensuing year

Laryngo-phoniatry

Ten lectures on this subject will be given from May 31st to June 5th at the Hôpital Bellan, 7, rue du Texel, Paris XIV Further information may be had from Dr Jean Tarneaud, 27, avenue de la Grande Armée, Paris XVI

Eradication of Bed-bugs

In view of the attention which is being devoted by local authorities to the eradication of the bed bug from houses the Royal Sanitary Institute has arranged two courses of training in the work of disinfestation They will begin on Tuesday, May 18th, and on Monday, June 7th Full particulars may be had from the secretary of the institute, 90, Buckingham Palace road, London, S W 1

Society for the Provision of Birth Control Clinics

A lecture on the theory and practice of contraception will be given to medical practitioners and medical students by Dr Greta Graff on Friday, April 2nd, at 6 P M , at the Walworth Women's Welfare Centre, 153A, East-street, S E Practical demonstrations will be given on Friday, April 9th, at 6 P M and at 7 P M The lecture and demonstrations will be open to medical practitioners and to all students who have completed their gynæcological course Tickets may be had in advance from the secretary of the society, 153A, East street, S E 17

Royal Veterinary College, London

A new governing body of this college has been set up in accordance with the royal charter granted last year The Duke of Gloucester is the president of the court of governors, and there are six vice presidents including Sir John McFadyean Among the bodies nominating members of the court and of the executive council are the County Councils Association, the Medical Research Council, the Corporation of London, the Privy Council, the Ministry of Health the Colonial Office, the University of London, and the Royal Society Under the charter the name is changed to the Royal Veterinary College and Hospital

West London Hospital

Queen Mary has consented to visit this hospital on Oct 18th to open the new extension

Nurses' Home at Walton Hospital

The Lady Mayoress of Liverpool on Feb 25th opened the new extension to the nurses' home at this hospital It has cost £43,290 and provides accommodation for 166 nurses

Dewsbury Infirmary

A Coronation appeal for £50,000 is being issued on behalf of this hospital It is to be on a seven years' plan, any promise made by a donor being divided into 14 half yearly payments The money raised is to be utilised to pay off the debt on the new infirmary and to provide for the extension of the nurses' home and other necessary enlargements

Kidderminster Hospital

Carpet and other firms have offered to pay the accumulated debt of this hospital, which amounts to £9168, provided that schemes of extensions are abandoned until income and expenditure balance, and 'that no member of the medical profession or the hospital staff (medical or otherwise) be allowed to act in any executive capacity at the hospital, or to serve as an ordinary member of any committee, the function of the staff to be purely advisory without any power to vote on questions of finance or policy "

Glasgow Royal Maternity Hospital

Mr Archibald Walker has given £25,000 to this hospital

Kettering General Hospital

Mr Alan Timpson has announced that he intends to double his gift of £5000 to this hospital

Royal National Hospital for Rheumatic Diseases, Bath

The Duchess of Kent has agreed to become president of this hospital

New Convalescent Home at Mitcham

On March 1st Sir Kingsley Wood laid the foundation stone of a new convalescent home at Mitcham It is the gift of Mr I H Wilson, the donor of Wilson Hospital, and there will be fifty beds

Appointments

BEYNON, JOHN M B Lond has been appointed Hon Medical Registrar to the Royal Sussex County Hospital Brighton

BRADBEER, W H M S Lond , D L O Hon Aurist and Laryngologist to Torbay Hospital, Torquay

DAVISON M H A , M D Durh , ' Morning List ' Anæsthetist for the Royal Victoria Infirmary, Newcastle-upon Tyne

GIFFORD E H W , M B N Z Resident Medical Officer at the Royal Cancer Hospital (Free) London

HUGHES JOHN B Chir Camb , F R C S Eng Clinical Assistant to the Surgical Department of the Sheffield Royal Infirmary

NOTES, COMMENTS, AND ABSTRACTS

INFLUENCE OF SCHOOL ROUTINE ON THE GROWTH AND HEALTH OF CHILDREN

BY JOHN ALLAN

THE possibility that school routine may be a factor of importance in the development of children seems to have been strangely neglected. In the past studies of growth have taken little account of periodic changes in the environment of the child and have been concerned mainly with standards of height and weight rather than with growth. Investigations carried out during the last fourteen years show that significant changes of growth rate occur during each school term. It is difficult to resist the conclusion that the school environment is directly responsible for these changes.

MATERIAL

The bulk of the material on which this study is based was collected in a boarding school in the south of England between 1923 and 1932. Unfortunately the numbers of boys in the school were small, ranging from 60 to a little over 90, so that averages for any one term were derived from somewhat limited figures. The total figures for the whole eight-year period reach quite large numbers and the consistency of behaviour in each term was very striking. This in conjunction with evidence from a number of other schools, makes one confident of the validity of the results presented here. As to conditions in the school it should be stated that diet was ample and satisfactory in quality and content, hours of work, exercise, and rest were carefully adjusted to the estimated needs of growing children, and there was opportunity for an unusually wide range of activities and interests out of school hours. The ages of the children ranged from 11 to 19 years.

METHOD

Each boy was weighed, measured, and examined at the beginning and end of term, and measurements of height and weight only were taken at intervals of four weeks. All measurements were taken without clothing and at the same time of day on each occasion, a steelyard type of weighing machine was used. In this way a series of measurements was obtained giving precise information about growth changes in each third of the term.

WEIGHT AND HEIGHT CHANGES

For the final analysis each increment was expressed as a percentage of the previous measurement before averaging. It was at once obvious that more weight was gained in the first month of term than in the second, and more in the second than in the third. Although many would lose some weight during the final month, a few even losing more than they had gained in the previous two months in general 70–80 would show a gain in weight for the term as a whole. When the increments for each month of the whole period were totalled, averaged and plotted, as in Fig. 1, a picture was obtained which showed the trend of fluctuations observable in each year, and among children in all age groups.

It is noticeable that at this school the rate of increase in weight during the holidays is much below that for the early portions of the spring and autumn terms. As the rate of energy expenditure during the term must have been very much higher than that for the holidays, it is probable that the gain during the term represents a gain of bone and muscle. A number of considerations lead to the tentative conclusion that at this school the retardation during the final months might be due to the monotony inseparable from institutional life rather than to actual pressure of work and play. Comparison made with sample figures from other schools make it probable, nevertheless, that in many schools pressure of work plays an important part in its causation.

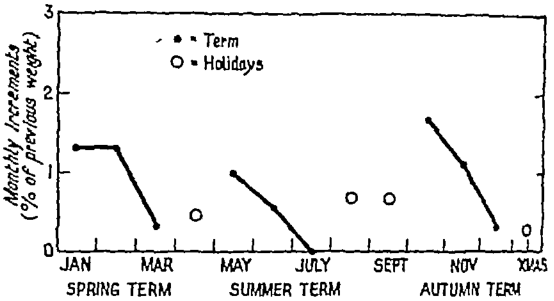

FIG. 1.—The average monthly increments in weight in a school of boys aged 11–19 years. The numbers measured varied from 478 in August and September to 650 in December.

Figures for height increments show a similar trend during the terms but over a much smaller range. In this case a slightly higher rate of increase is found during the holidays than in any month of any term, the spring holidays showing the highest increase of all. In general the extra growth recorded for the holiday periods may be largely attributable to a reduction of the mechanical pressures imposed on the compressible intervertebral discs by such activities as gymnastics, games and athletics.

In both height and weight there are periods of reduced growth rate occurring towards the end of each term of the school year. The regularity of the form of the fluctuations would lead one to suppose that seasonal and climatic factors have no great influence where schools in the south of England are concerned.

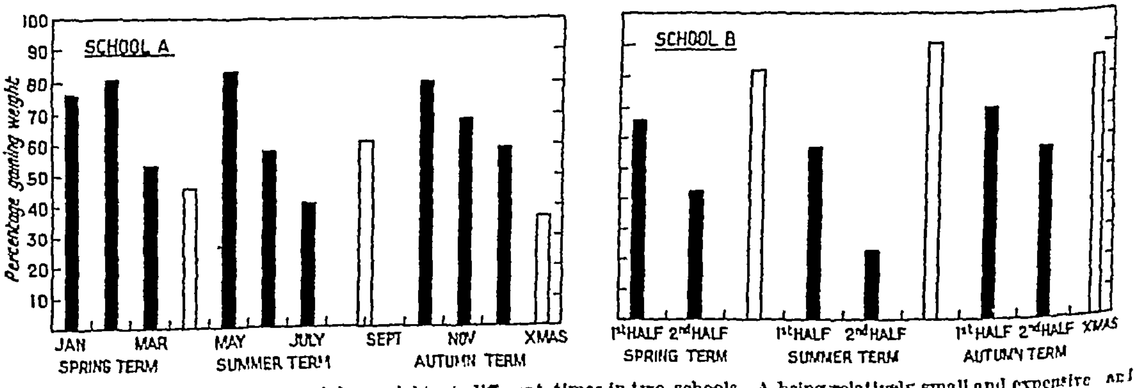

FIG. 2.—The proportion of pupils gaining weight at different times in two schools, A being relatively small and expensive and B large and less well to do.

COMPARISON OF SCHOOLS

An interesting comparison of the records of two schools is presented in Fig 2 * This shows the proportion of boys at each of two schools who gained weight in term and holiday time during 1926 School A was relatively small while school B was very large and had a rigorous and rather formal routine with greater pressure of work and play and less time allotted to rest and sleep Diets at both schools were satisfactory and the range of ages was virtually identical. Both schools were situated in pleasant country in the South of England During the slightly longer intervals between weighings at B rather fewer children gained weight but the trend downwards at the end of term was similar for both During the holidays the contrast is great a very high proportion of boys from B gaining weight on each occasion making it appear that some compensatory acceleration was taking place It is *significant to note that the children attending B* come, in the main from less well to-do homes than those attending A where the fees are very much higher

This peculiar difference in holiday behaviour noticeable in other years as well may form the basis for a rough assessment of the relative severity of routine in different schools of a similar type A comparison of the percentages of children who gain weight during the term and holiday times will give *an indication of the position* The *higher the percentage* who gain during the holidays the more strenuous and exacting the régime The converse must not be considered to have any significance if the children come from poor homes

INCIDENCE OF ILLNESS

Studies of the incidence of illness at school A show a pronounced tendency for the bulk of sickness and disability to occur in one or other of two well defined periods of the term One of these periods when a high incidence of illness may be expected is at about the third week of term while the other occurs about the eighth or ninth week It seems to be rare for an epidemic to occur or reach its peak during the middle four weeks of term.

SUBNORMAL NUTRITION

Material obtained from these figures relating to children from prosperous homes provides a good basis for comparison of standards of nutrition and growth It is remarkable to find that in an area of south-east London there are comparatively few children who show any serious signs of defective nutrition. In the main they appeared to be sturdy robust and active but on comparing their height for age with the standard achieved by children in prosperous boarding schools it was *found that many* were a full two years behind Hereditary factors may have played some part but it would be surprising if they were sufficient to account for the 70 per cent who were an inch or more below the average for their age on the standard of the well nourished. Moreover the children concerned were not drawn from a slum area and the parents of the majority were in employment It seems probable therefore *that stunted height resulting from defective* nutrition will tend to mask the real state of affairs throughout the country The danger that much malnutrition will be passed over is particularly great in view of the recent change of policy of the Board of Education Medical Authorities which is outlined in the latest annual report of the chief medical officer (The Health of the School Child Report for 1935 H.M.S.O 2s 0d) From this it appears that estimates of nutritional states are now being based on clinical observations only standards of height and weight for age being no longer applied In this way only the grossly undernourished will be recorded and the general nutrition of the child population will be made to appear much better than is actually the case

CONCLUSIONS

It should not be assumed that the present organisation of school routine is satisfactory in relation to the growth and health of children. There is evidence to show that the effects may even be detrimental to development.

It seems desirable that a close study should be made of the influence on growth and health of schools of different types Much remains to be learnt concerning the effects of school routine on growth and health With our present knowledge it is unsafe to assume that any of our schools are providing the best possible environment for development

---

* I am indebted to Dr G E Friend of the Medical Officers of Schools Association for permission to make use of his records published in "The Schoolboy His Nutrition and Development"

SCIENCE AND BUILDING

By the enterprise of the directors of the Building Centre in New Bond street the Department of Scientific and Industrial Research has been enabled to stage a very interesting exhibition at this centre And this is of importance because as the guide suggests, it is probably true to say that it has been left untouched to a greater extent than any other major industrial activity by the developments in science and technology of the last hundred years'

The exhibits from the Building Research Station include a section devoted to concrete, showing by graphs and descriptive matter how much the strength of concrete depends on its water content and the absence of air voids Samples are shown of the light weight aggregates which are used increasingly for concrete partition walls and casing for steel work. Plastering materials are apt to dry too slowly or too rapidly but the rate of drying can be controlled Deterioration of paint over plaster may be due to mere blistering and peeling owing to imprisoned water or to chemical action of alkaline materials on such paints as Prussian Blue

The Fuel Research Station illustrates the properties of various fuels, the radiant efficiency of open fires and the measurement of smoke emission from domestic fires

Among the exhibits from the Forest Products Research Laboratory is one showing the resistance of different timbers to erosion Rhodesian teak and Canadian maple wear more smoothly as flooring than oak birch jarrah or coniferous woods.

The National Physical Laboratory has exhibits of illumination and models of rooms with and without noise reducing devices; noise producers and telephones allow the visitor to make practical comparisons for himself Studies of wind pressure on buildings, vibration of roads and buildings and movement of the masonry of the Tower of London are illustrated and explained

Water softening by base-exchange materials, including some British clays and synthetic resins, contamination of water by lead and filters for removal of that metal and other such matters are set out in a joint exhibit of the Water Pollution Research Board and the Chemical Research Laboratory

This exhibition should be of value to all who may have to advise on the building of hospitals or other institutions and should help them to avoid mistakes which are sometimes made when materials are chosen for their artistic effect when new rather than for their permanent value in practical use

The exhibition closes on March 25th

DURATION OF LIFE IN FOSSIL MAN

An attempt to determine how long men lived in the remote ages has recently been made by H V Vallois a French anthropologist (*C.R Acad Sci Paris* Jan 4th 1937 p 60) The varied phases of eruption of the teeth and ossification of the limb bones may suffice to indicate the age of infants and adolescents but the problem proves much more difficult when adult bones are examined Vallois states that attrition of the teeth is an unreliable guide, since this occurred much earlier in prehistoric times than in living man, but more accurate work on synostosis of the cranial sutures enabled him to employ this sign as a basis in his investigation The remains of 173 men, women, and children of the palæolithic and mesolithic ages were studied, some by Vallois himself, and the data relating to the rest being deduced from descriptions published by other workers Piltdown man, pithecanthropus, and sinanthropus were not included in the survey

It was found that 45 of these prehistoric people died during the first decade and 17 in the second Thereafter Vallois separates the sexes and finds that in the third decade the females have a higher survival-rate, the figures being 27 against 17 The position is then reversed in favour of the males aged thirty to forty, when the figures are 12 against 7, and this superiority is conspicuous in the fifth decennium, *only 1 woman surviving to 10 men* Only 3 lived to be over fifty, and none showed the complete *synostosis commonly seen in adults after seventy or* eighty years of age It may be objected that the fragile skulls of old people would not be preserved, but it is pointed out that many even more delicate skulls of children have been discovered With regard to synostosis of the cranial sutures Vallois is of opinion that in fossil man the tendency would have been to an earlier fusion, since in primitive races it occurs a little earlier than in the civilised, while in anthropoids the cranium is completely ossified at an age equivalent to twenty-five years in man

The figures cited seem to indicate that fossil man was short-lived, only 10 of 39 men and 1 of 35 women reaching the fourth decade In these early ages man appears to have been subject to the law which governs savage mammifers, that death coincides with the decline of physical strength and sexual activity

In our issue of Feb 27th (p 517) we gave the price of the revised edition of Prof Curtis Hilliard's Textbook of Bacteriology and its Applications (London Ginn and Co) as 12*s* 6*d* Copies of the earlier edition of the book can still be supplied at this price, but the publishers inform us that the price of the new edition will be 15*s*

HEART DISEASE WITH NORMAL RHYTHM COMPLICATING PREGNANCY

A SERIES OF ONE HUNDRED CASES

By Kenneth Harris M.D Camb F R C P Lond
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL

The successful management of a normal pregnancy and labour is a subject to which an increasing amount of attention has been directed in recent years and is a matter that concerns both the physician and the obstetrician.

When pregnancy is complicated by chronic heart disease, it is of considerable importance that an attempt should be made to estimate the capacity of the patient's heart in relation to the increased strain on her cardiovascular system consequent on pregnancy Upon the power of adjustment of the heart may depend the successful delivery of a living child and the prevention of serious complications in the mother as well as the maintenance of the patient's health so that she is able to lead as nearly a normal life as possible.

A patient with valvular disease of the heart may seek advice from a doctor as to the advisability of pregnancy and the risks involved in both pregnancy and labour The enlarged uterus and the extra placental circulation required to maintain adequate nutrition of the fœtus will throw an increased burden on an already damaged heart moreover labour and the puerperium with the possible demands of lactation will also tax the resources of an inadequate cardiovascular system. Such things as the condition of the myocardium as shown by exercise tolerance congestive heart failure and the size of the heart will have to be carefully investigated, since each of these may have an important bearing on the prognosis

It is the purpose of this paper to show the effect of pregnancy and labour on women suffering from valvular disease of the heart with normal rhythm The problem is approached from the point of view of the physician who is concerned not merely with the care of the patient during her pregnancy but with her subsequent medical history For this purpose a series of 100 cases has been recorded in which the patient and her cardiac condition have been kept under observation for periods varying from two to four years Whilst this series was being collected only one case of auricular fibrillation was found it was, therefore decided to omit this case and to present this series as one of 100 cases of normal rhythm It may be remarked in passing that this percentage of cases of auricular fibrillation (1 per cent.) is abnormally low when compared with series recorded by other observers

The cases for observation were taken in order of their attendance at the antenatal and the medical out patient department of University College Hospital and the main object of the investigation was to complete a follow up of the cases over a period of at least two years Actually only 3 cases were lost sight of whilst 20 patients have been followed up for four or more years.

Of the various papers published on the subject during the last ten years reference will be made only to those in which histories of the patients have been followed up for a period of some months or years.

In 1926 a report on a group of 166 cases mainly from Guy's Hospital which had been investigated by Hunt was published after his death by Campbell. Hunt had followed up 98 of these patients after delivery; he attached considerable importance to the size of the heart and he also found that auricular fibrillation was a disastrous complication of heart disease in pregnancy

Corwin, Herrick, Valentine and Wilson (1927) carried out an analysis of 196 cases of valvular disease of the heart in pregnancy among patients attending the Sloane Hospital New York including an investigation of the after histories of 109 cases over periods varying from two months to two years Their investigation was mainly directed towards the effect of the cardiac condition on the management of pregnancy and labour rather than a consideration of the subsequent medical history

McIlroy and Rendel (1931) published a very full and comprehensive paper on their observations on 200 cases, mainly from the obstetrical point of view They were of the opinion that multiple pregnancies tended to lower the cardiac efficiency permanently They found that the anatomical lesion appeared to have little bearing on the prognosis They stressed the functional efficiency of the heart as a factor of importance

Crighton Bramwell (1931) presented a paper before the Royal Society of Medicine recording the results of an investigation of 82 cases carefully observed and followed up In 1935 he published a second paper in which the number of cases had been increased to 300—this included the original 82 cases. Of these cases 95 out of the first 150 had been followed up for various periods up to five years He found that patients admitted as emergencies were in a more serious condition (9 deaths out of 13 cases) than those who had been under medical supervision in the antenatal department (only 8 deaths out of 287) When first seen 21 had congestive heart failure and the prognosis in cases with this complication was grave There was auricular fibrillation in 16 (5 3 per cent.) and this was a serious complication. Concerning the degree of cardiac enlargement Bramwell stated that the bigger the heart the smaller the reserve and that other things being equal the presence of great cardiac enlargement added to the seriousness of the prognosis He did not think that the type of valvular lesion offered any help in the prognosis The outlook was worse in the first pregnancy than in other pregnancies; the mortality for the whole series was 5·7 per cent but in primiparæ the death rate was 9 per cent compared with 2 6 per cent in multiparæ He stressed the great value of adequate antenatal supervision

The mortality in the above mentioned series varied from 2 5 per cent (McIlroy and Rendel) to 11 per cent. (Hunt)

The incidence of congestive heart failure in the published series also varies considerably This difference can be easily accounted for since in some papers the figures are based on the number of patients showing congestive failure on admission whereas in others all cases developing congestive failure during the course of the pregnancy are included. Thus Bramwell found 21 out of 300 (7 per cent.) had congestive heart failure at the time of their first attendance whereas McIlroy and Rendel found that congestive heart failure occurred in the course of pregnancies on 51 occasions in 226 patients (22 5 per cent.)

Ætiology

The 100 cases in this series are examples of chronic valvular disease of the heart with the exception of one patient who was admitted as a cardiac case but who gave no history of rheumatic fever; she was found to have free aortic regurgitation due to a streptococcal endocarditis arising from pyorrhœa

In the whole series 65 per cent were definitely rheumatic Of these 35 patients gave a history of previous attacks of rheumatic fever of whom 5 had additional symptoms, 2 had had severe or frequent attacks of tonsillitis, 2 had suffered from growing pains in childhood, and 1 had had both growing pains and tonsillitis There were 12 patients who had suffered from both rheumatic fever and chorea The remaining 18 gave a history of chorea, of whom 1 had also had growing pains and 3 had had tonsillitis

A group of 16 patients gave a history of conditions not infrequently rheumatic in origin Of these, 11 had had tonsillitis, 3 had suffered from tonsillitis and growing pains, and 2 from growing pains only If these cases are included with the cases of rheumatic fever and chorea, the total would be 81 per cent

The remaining 19 patients gave no history of previous rheumatic fever, chorea, growing pains or tonsillitis

This series may, therefore, be taken as fairly representative of an average series of cases of valvular disease of the heart among young adults No definite difference in the prognosis or in the subsequent course was found between the rheumatic and non rheumatic group Moreover, in the 18 cases of congestive heart failure, the same proportion of rheumatic and non rheumatic cases was maintained—namely, 66 7 per cent *(12 out of 18 cases)* as compared with 65 per cent for the whole series

The Heart

Valve lesions—On considering the type of valve lesion occurring in the series, 81 cases of mitral stenosis, unaccompanied by other valve lesions, 13 cases of mitral stenosis and aortic regurgitation, and 6 cases of aortic regurgitation alone were found There was an associated high blood pressure in 3 of these cases, 2 of whom died, one of cerebral hæmorrhage and the other of cerebral thrombosis complicating congestive heart failure No difference was found in prognosis between cases of mitral stenosis and those of aortic regurgitation or those in whom both these lesions were present

The *size of the heart* has been carefully estimated at the time of the patient's first visit during the pregnancy and has been reviewed at intervals after delivery In all cases where there seemed to be any doubt as to the size of the heart, a radiogram at two metres or an orthodiagram has been taken The cases have been divided into two groups —

(1) Those having little or no clinical enlargement

(2) Those having moderate or considerable enlargement

The death rate was higher in the second group than in the first, the mortality being 16 3 per cent (7 out of 43 cases) as compared with 9 1 per cent (7 out of 77 cases) A comparison of the results at the end of two years revealed that the cases with little or no clinical enlargement did slightly better than the others Out of the former group 55 8 per cent were unchanged—i e, either free of symptoms or in statu quo—but only 35 9 per cent of the latter group were unchanged at the end of two years Thus patients in whom the heart was not clinically or only slightly enlarged did a little better than those in whom moderate or considerable enlargement was present

In any group of patients in whom valvular disease is present, however, similar results would be obtained when the cases are followed up over a period of two years Although the size of the heart is helpful in the prognosis of any cardiac case, it should not be unduly stressed in estimating the risk of pregnancy in a patient with valvular disease

Exercise Tolerance

The history of each patient has been carefully investigated, special attention has been paid to the amount of work and exercise that the patient has been able to undertake before she became pregnant and also during the early months of her pregnancy In the case of the multipara, inquiry has been made into the previous history of her former pregnancies and labours, and the time of breakdown of exercise tolerance, if any, in relation to the stage of the pregnancy A simple exercise tolerance test has been used in these patients to control conclusions arrived at from the history given, it was essential that the exercise should be simple and easily carried out in view of the pregnancy The method adopted has been to make the patient sit up and down and to touch her toes ten times, whilst on the examination couch, the pulse and respiration rates have been counted immediately before and after the exercise and again after two minutes' rest in the supine position

The exercise tolerance has been investigated at the time of the first examination during the pregnancy and subsequently at each attendance in the out patient department after delivery—i e, at six months, one year, and two years The alteration in the patient's exercise tolerance existing at the end of two years after delivery has been found to be almost invariably the same as that found at six months after delivery This was so in 73 out of 85 cases (85 9 per cent) seen at both six months and two years, 2 of the remaining 12 were better and the other 10 were worse at two years than at six months after delivery

Three patients (Cases 1, 2, and 3), who gave a history of earlier and earlier breakdown of exercise tolerance in successive pregnancies, did badly, two (Cases 2 and 3) developing congestive heart failure and one (Case 1B) dying soon after delivery The following is a typical example of such a case —

Case 3 first came under observation during her third pregnancy Her first pregnancy was seven years previously, when she had been confined to bed for two months after delivery owing to dyspnœa, although there had been no shortness of breath during the course of the pregnancy Five years ago she had her second pregnancy and dyspnœa commenced in the 6th month During the third pregnancy her exercise tolerance broke down at the 3rd month and congestive heart failure developed in the 9th month

Three patients (Cases 4A, 5, and 6A), who gave a history of early onset of dyspnœa and failure of exercise tolerance during the first pregnancy, developed congestive heart failure during the second pregnancy Two more patients (Cases 7 and 8), who gave a similar history of early exercise tolerance breakdown, died soon after labour, one after the second pregnancy and the other shortly after the first labour

From observation of these cases it seems that (1) early breakdown of exercise tolerance in a primipara is a grave sign—accordingly, a careful investigation of the history of the patient's exercise tolerance during the early months of her pregnancy is of great value, and (2) in multiparæ, the experience derived from the previous pregnancies is of great value, since the breakdown of exercise tolerance earlier and earlier in each successive pregnancy is a serious feature

Congestive Heart Failure

Of the 100 patients 18 developed congestive heart failure during the course of the pregnancy, in one patient congestive failure occurred in both her pregnancies, so that the incidence was 19 in 120 pregnancies (15 8 per cent) No patient in this series died during pregnancy or labour, but during the period following delivery when they were under observation, the mortality for those patients was

22 2 per cent. (4 out of 18 cases); whereas in those who had not had congestive failure the mortality was only 12 2 per cent (10 out of 82 patients) The mortality was higher when congestive heart failure occurred during the course of the first pregnancy than when it developed in a multipara. There were 5 primigravidæ who went into congestive failure, and 2 (40 per cent.) subsequently died 14 multiparæ had congestive failure during the course of the pregnancy and 2 (14 per cent) have since died.

Congestive heart failure has been found to appear at any time during the course of the pregnancy having been seen in the earliest stages and also just at full term The relationship between the time of onset and the subsequent prognosis of the case has been considered and the following results have been noted.

In 8 of the 19 cases congestive failure developed early* in the pregnancy whilst in the remaining 11 congestive failure came on in the later half of the pregnancy In the latter group 6 of the patients gave a history of early breakdown of exercise tolerance although the congestive failure did not occur till late but in the remaining 5 it was impossible to say whether the exercise tolerance broke down early or late in the pregnancy since the history given by the patient was too indefinite

None of the group of 8 patients, in whom congestive failure developed early went to full term: 1 had a spontaneous abortion 2 were induced and the remaining 5 had hysterotomy performed From the cardiac aspect all these patients did well with the exception of the patient who had a spontaneous abortion in her second pregnancy; she died in congestive heart failure having had failure also in her first pregnancy It is probable that the successful results in these patients depended largely upon the treatment adopted in each case When congestive heart failure developed towards the end of pregnancy the patients did badly 3 out of the 11 dying shortly after delivery

If the patient was admitted to hospital in time to enable suitable therapeutic measures and rest to be carried out before delivery and if as a result she was no longer in congestive failure the prognosis became more favourable Thus only 1 patient died out of the 11 in whom congestive failure had disappeared at the time of delivery whereas 3 died out of 7 patients in whom delivery took place while signs of congestive failure were still present.

Occasionally cases occur in which congestive heart failure does not react to appropriate medical treatment In the later months this may be the result of the mechanical effect of pressure by an enlarged uterus interfering with the normal action of the heart and lungs In the earlier months however this mechanical factor is not present and the congestive heart failure must result from the extra load thrown upon the heart from the vascular changes occurring in the enlarging uterus This is supported by a case in this series in which progressive congestive failure in the early months of pregnancy cleared up rapidly after artificial termination

Case 2 was admitted to hospital in 5th month of pregnancy in congestive heart failure; after 8 weeks of treatment it was decided to induce premature labour at the 31st week of pregnancy since the congestive failure was progressive After delivery she made an excellent recovery and the congestive failure rapidly cleared up She was alive but worse 4 years after delivery

It is fairly widely held (Pardee 1922 Corwin et al 1927) that induction of abortion or premature labour during congestive heart failure almost invariably leads to a fatal result. Two cases in this series were induced in such circumstances; both survived and lived for more than two years. One (Case 2) has just been described the other is the following:—

Case 9 primigravida first entered hospital at 3rd month of pregnancy with congestive heart failure; she failed to react to treatment and as the congestive failure was increasing induction was carried out at 27th week. The progress of the congestive failure was arrested but did not clear up She was readmitted 2½ years later twenty weeks pregnant since she was still in congestive failure She died 13 days after spontaneous abortion

Two other patients in whom congestive heart failure was present in one pregnancy subsequently became pregnant again both cases went through the next pregnancy and were successfully delivered at full term without the development of congestive failure (Cases 5 and 10) This was attributed to earlier and better supervision during the antenatal period owing to the experience gained during the conduct of the former pregnancy

Since the onset of congestive heart failure was a serious feature during the course of pregnancy the previous history of those patients who developed congestive failure was investigated Short intervals between pregnancies seemed to be a factor in the production since in 5 out of 6 multiparæ the interval between the former pregnancy and the one in which congestive failure developed was under two years The length of time between the pregnancy in which congestive failure occurred and the rheumatic infection which may have caused the heart lesion (when known) did not appear to have any significance Early breakdown of exercise tolerance was important In 3 cases in which exercise tolerance broke down early in the first pregnancy congestive failure developed in the second pregnancy (Cases 4A, 5 and 6A) Of 9 patients who had had several children 3 gave a clear history of earlier and earlier breakdown of exercise tolerance in former pregnancies and developed congestive failure in the pregnancy during which they came under observation

The incidence of premature delivery was 42 9 per cent in those cases who had had congestive heart failure during pregnancy being much greater than in those who did not have failure (14 6 per cent.). The incidence of premature delivery in the whole series was 16 5 per cent †

Follow-up Results

All cases have been examined personally at 6 months, 1 year and 2 years after delivery Three [illegible] who did not attend for various reasons [illegible] change of address were traced by the [illegible] and the district midwives, to whom [illegible] indebted for this assistance In 5 cases a personal visit was made to the patient's home and [illegible] examined in her own home. Only 3 [illegible] of the 100 patients have been lost sight of [illegible] period of 2 to 4 years

In this way 97 cases were [illegible] under observation. Of the 3 cases [illegible] of two could not be traced [illegible] known to be alive and doing her housework [illegible] after delivery but refused any examination [illegible] had however been examined 1½ [illegible] and was then free of symptoms

The mortality [illegible] 14 per cent [illegible] patient died during [illegible] labour (Table [illegible] The number of [illegible] here is high [illegible] compared with [illegible] of other [illegible] because the period of observation has been longer than in many of the series hitherto published, and also because the total has included 4 non cardiac deaths These 4 deaths were due to cerebro spinal meningitis (Case 14A), influenzal septicæmia (Case 13), septic peritonitis (Case 12), and rupture of the aorta (Case 11A), in the latter the aorta was quite healthy and the rupture was in no way connected with the cardiac condition The puerperal mortality—i.e , deaths occurring within six weeks of delivery—excluding those who died of non cardiac causes, was only 5 per cent (Cases 1B, 15, 16, 17, 18)

---

* Early pregnancy has been taken as the 1st to 4th month; late pregnancy from the 5th month to full term

† It has [illegible] the incidence [illegible] delivery [illegible] given by [illegible] Recent [illegible] 16 per [illegible] 14 2 per [illegible] per cent

TABLE I—*Deaths*

Case No	Valve lesion	CHF	Treatment	Date of death	PM	Cause of death
			A —NON-CARDIAC DEATHS			
11	MS	0	1st normal labour 2nd spontaneous premature labour	1¼ yrs 3rd day	Yes	Rupture of normal aorta
12	"	0	Hysterotomy at 26th wk	4th day	No	Septic peritonitis
13	"	0	Normal labour	17th day	No	Influenza vera and streptococcal septicæmia
14	"	0	1st } normal 2nd } labour	1 yr 2nd day	No	Cerebro spinal meningitis
			B —DEATHS DURING PUERPERIUM			
1	MS and AR	0	1st forceps at full term 2nd } normal 3rd } labour	3½ yrs 1¼ yrs 1½ mths	No	CHF
15	MS	+	Cæsarean section	6th day	No	Post-operative broncho pneumonia
16	MS and AR	0	Delivery of breech by intra uterine manipulations	3 hrs	Yes	Post-partum hæmorrhage and shock
17	"	+	Forceps at full term	7th wk	No	CHF
18	AR	0	Normal labour	8th day	Yes	Acute infective endocarditis
			C —OTHER DEATHS			
7	MS	0	*Manual rotation and forceps*	6¼ mths	Yes	*Acute heart failure*
8	MS	+	Normal labour	2nd mth	Yes	CHF
9	"	+	1st, induction at 27th wk 2nd spontaneous abortion at 20th wk	2¼ yrs 13th day	Yes	CHF
19	MS and HBP	0	Normal labour	6¼ mths	Yes	Cerebral hæmorrhage
21	AR and HBP	0	Induction at 12th wk	4 mths	Yes	Cerebral thrombosis

MS = Mitral stenosis AR. = Aortic regurgitation
HBP = High blood pressure CHF = Congestive heart failure
PM. = *Post mortem examination*

The patients who were still alive at the end of 2 or 4 years have been placed in three groups those who were free of all symptoms (10 cases), others in whom the cardiovascular system seemed unchanged (35 cases), and the remainder who were definitely worse after than before the pregnancy (38 cases) These results were arrived at by carefully comparing the condition of the heart and the results of the exercise tolerance tests, as well as the patient's history, at the time of the final examination, with the notes made at the time of the first examination The results are shown in Table II, it will be seen that just half of the whole series were worse or dead at the end of two years

TABLE II—*Results of Follow up*

—	Total (100)	At 2 yrs	At 4 yrs
Free of symptoms	11*	10	0
Unchanged	37†	25	10
Worse	38	28	10
Dead	14	12	[illegible]

* Includes 1 lost sight of at 1¼ years
† Includes 2 lost sight of, at 1 and at 1¼ years respectively

Summaries of Cases Quoted

CASE 1

FIRST PREGNANCY —Primipara aged 22 *Heart* Fair exercise tolerance, not clinically enlarged, M S and A R ‡, rheumatic fever at 16 years *Course* A few attacks of paroxysmal tachycardia *Delivery* Forceps at full term owing to paroxysmal tachycardia during labour, female child, 6 lb 10 oz *Follow up* Pregnant again

A. SECOND PREGNANCY —*Course* 8 or 9 attacks of paroxysmal tachycardia *Delivery* Normal labour at full term, female child, 7 lb 1½ oz *Follow up* Pregnant again

B THIRD PREGNANCY —*Course* Frequent attacks of paroxysmal tachycardia *Delivery* Normal labour premature female child, 6 lb *Death* At home from C H F at 1½ months after this and at 3½ years after first labour

CASE 2

Aged 34, 3 para *Heart* C H F developed at 4th month, slightly enlarged, M S, rheumatic fever and chorea at 10 years *Course* C H F did not clear up with rest, &c *Delivery* Induction of labour at 31st week *Follow up* C H F cleared up rapidly after delivery Sterilisation at 6th month after labour At 4 years, worse

CASE 3

Aged 34, 3 para *Heart* C H F at 8½ months, moderately enlarged, M S, no rheumatic history *Course* C H F not quite cleared up at time of labour *Delivery* Normal labour at full term, female child, 5 lb 15 oz *Follow up* At 4 years, worse

CASE 4

FIRST PREGNANCY —Primipara aged 27 *Heart* Poor exercise tolerance, slightly enlarged, M S, chorea at 7 years *Delivery* Normal labour premature male child, 6 lb 2 oz *Follow up* Pregnant again

A. SECOND PREGNANCY —*Course* During this pregnancy developed C H F at 8th month C H F cleared by time of operation *Delivery* Cæsarean section and sterilisation at full term, male child, 6 lb 1 oz. *Follow up* At 2¼ years after former labour, worse

CASE 5

FIRST PREGNANCY —Aged 25 2 para *Heart* Poor exercise tolerance, moderately enlarged, M S, growing pains as a child *Course* C H F developed at 8th month gone at full term, exercise tolerance broke down at 3rd month *Delivery* Normal labour at full term, male child, 5 lb 10 oz *Follow up* Pregnant again

A SECOND PREGNANCY —*Course* No C H F during this pregnancy *Delivery* Normal labour at full term male child 7 lb 3 oz *Follow up* At 2¼ years after former labour, worse

CASE 6

FIRST PREGNANCY —Primipara aged 35 *Heart* Good exercise tolerance, not clinically enlarged, M.S, rheumatic fever at 15 years *Delivery* Breech delivery at full term male child 5 lb 2 oz. *Follow up* Pregnant again.

---

‡ Abbreviations as in Table I

A. SECOND PREGNANCY —*Course* C H F at 3rd month clearing up by time of operation. *Delivery* Hysterotomy and sterilisation at 4th month *Follow-up* At 2½ years after this and at 3½ years after former delivery worse

CASE 7

Aged 23; 2-para *Heart* Very poor exercise tolerance moderately enlarged M.S chorea at 13 years. *Delivery* Manual rotation and forceps premature male child. *Death* At 6th month acute heart failure P.M.

CASE 8

Primipara aged 25 *Heart* Poor exercise tolerance; slightly enlarged M.S no rheumatic history *Course* Exercise tolerance broke down at start of pregnancy C.H.F developed at full term *Delivery* Normal labour at full term male child 5 lb 1 oz. *Death* At 2nd month C.H.F P.M

CASE 9

FIRST PREGNANCY —Primipara aged 24 *Heart* C H.F at 2nd month slightly enlarged M S; chorea at 7 and 14 years *Course* C H F progressive in spite of rest &c *Delivery* Induction of labour at 27th week *Follow-up* Pregnant again

A. SECOND PREGNANCY —*Course* C H.F had persisted since 1st pregnancy *Delivery* Spontaneous abortion at 20th week. *Death* At 2½ years after 1st delivery and on 13th day after abortion from C.H F P.M

CASE 10

FIRST PREGNANCY —Aged 36; 5 para *Heart* C H.F at 8th month moderately enlarged; M.S rheumatic fever at 12 years *Course* C H F cleared up by delivery *Delivery* Normal labour premature female child *Follow-up* Pregnant again.

A. SECOND PREGNANCY —*Course* No C H F during this pregnancy *Delivery* Normal labour at full term dead female child 5 lb 11 oz *Follow-up* At 4 years after this and 5½ years after former labour worse

Conclusions

1 A hundred cases of pregnant women suffering from valvular disease of the heart with normal rhythm have been examined during pregnancy Only 3 cases have been subsequently lost sight of the remainder have been kept under observation for at least 2 years after delivery and of these 20 have been followed up for 4 or more years No case died during the course of the pregnancy or labour

2 In the management of a case a careful investigation of the history of the patient s exercise tolerance before and during the early months of the pregnancy is of great importance Early breakdown of exercise tolerance in a primipara is a grave sign since death may occur soon after labour or congestive heart failure is likely to supervene with its attendant grave risks In multiparæ the experience derived from the previous pregnancies is of great value since the breakdown of exercise tolerance earlier and earlier in each successive pregnancy is a serious feature for the same reason.

3 The appearance of congestive heart failure is serious in a pregnant patient with cardiac disease The subsequent mortality was greater in those patients in whom this occurred than in those in whom it did not and particularly in the primipara Where congestive failure developed early in the pregnancy the cases did well possibly as a result of obstetrical treatment; those in whom the failure developed late did badly particularly if the failure had not cleared up at the time of delivery A short interval between pregnancies increases the risk of congestive failure in a cardiac case The incidence of premature delivery was much increased in cases developing congestive failure during pregnancy whereas it was not increased in the other cardiac cases

4. Cases with slight or no enlargement of the heart did better than those with moderate or considerable enlargement There appeared to be no difference in the prognosis between cases of mitral stenosis, those of aortic regurgitation and those in whom both these lesions were present.

5 Pregnancy is contra-indicated in those cases of heart disease with normal rhythm who have ever had congestive failure in whom the exercise tolerance broke down early in a previous pregnancy or where the heart is considerably enlarged. Where congestive failure appears early in the course of a pregnancy termination by emptying the uterus should be undertaken as soon as the failure has been relieved by rest and other medical measures During the pregnancy careful supervision and increased rest with admission to hospital for at least two weeks before the onset of labour is necessary for the successful management of a case of heart disease complicating pregnancy

I am greatly indebted to Prof F J Browne director of the Obstetric Unit and his staff, and to Sir Thomas Lewis and the physicians of University College Hospital for leave to examine and follow up this series of patients I also wish to thank Sir Thomas Lewis for his encouragement and advice throughout this investigation.

THE CHEMOTHERAPY OF TYPHOID AND SOME OTHER NON STREPTOCOCCAL INFECTIONS IN MICE

BY G A H BUTTLE, M.A. Camb M.R C S Eng
H J PARISH M.D., M.R.C P Edin
MORAG MCLEOD B Sc. Edin.
AND
DORA STEPHENSON Ph D Leeds
(*From the Wellcome Physiological Research Laboratories*)

FOLLOWING the work of Domagk (1935) on Prontosil, *p* aminobenzenesulphonamide was shown to be effective in the treatment of mice against intraperitoneal infection by streptococci (Tréfouël J and Mme Nitti and Bovet 1936 Buttle Gray and Stephenson 1936 Colebrook and Kenny 1936) and meningococci (Buttle et al. 1936; Proom 1937)

In this paper we describe the results obtained in treating mice infected with various other organisms—viz *Bacterium typhosum Bact paratyphosum* B *Bact aertrycke* pneumococcus Friedländer s bacillus and pasteurella The degree of protection is also compared with that previously reported from the Wellcome Physiological Research Laboratories for the hæmolytic streptococcus and the meningococcus

TECHNIQUE

Infection of Mice —A number of strains of each organism were obtained and the most virulent selected for this investigation All the organisms were grown for 18 hours in the medium described by O Meara and Brown (1930) the cultures were diluted in broth and 0·5 or 1·0 c.cm amounts injected intraperitoneally into mice of 25 to 30 grammes in weight Dilutions of some of the strains were also made in 5 per cent mucin, using a method similar to that of Miller and Castles (1936) in their work on the titration of antimeningococcus serum The mucin produced a considerable diminution in the minimal fatal dose, an observation which has already been made by Miller (1935) for the meningococcus, and by Rake (1935) for *Bact typhosum* The virulence of the strains tended to decrease when they were kept on artificial media, but was restored to some extent by mouse passage

Treatment with the Sulphonamide —The drug was given to the mice by mouth in suspension with gum acacia using a 1 c cm syringe with a blunted needle In preliminary experiments on dosage a single injection of 100 mg was tolerated by mice of 25 to 30 g , but produced a temporary paralysis with incoördinate movements of the limbs which lasted four to five hours Doses of 40 mg and 25 mg were therefore used for the present investigation and produced no symptoms

The general scheme of treatment was to give one group of mice a single injection of the drug, and a second group injections twice daily, commencing treatment in each case immediately after infection A third group received their first treatment five hours after infection, and thereafter two doses a day as for the second group

TABLE I

Treatment of Mice Infected with Bact typhosum (“ *Rawlings* ”—*rejuvenated*)

† Ten mice injected with mucin alone, and 10 mice injected with mucin and treated with the sulphonamide all survived

BACT TYPHOSUM

Three strains were used of approximately equal virulence—viz , “ Rawlings ” (rejuvenated), “ Allahabad,” and “ Mrs S ,” all of which were kindly supplied by Major J S Boyd, R.A M C Experiments have been made, with and without mucin, a typical protocol (strain “ Rawlings ”) being shown in Table I

In the first section of the experiment, no mucin was used to enhance virulence Of 20 treated mice (2 groups of 10 animals infected with 50 million organisms and treated immediately) 15 were alive twelve days after the injection of 100 times the number of organisms (500 thousand) required to kill all 10 control mice In the second section, in which mucin was used as a diluent for the culture, protection was obtained against a slightly larger number of fatal doses , a group of 10 treated mice, injected with 10 thousand times the number of organisms required to kill 4 of 10 controls, all survived for twelve days (In another experiment treated mice were kept for one month, and no deaths occurred after the twelfth day)

A single dose of 25 mg of the sulphonamide was almost as effective as doses of 25 mg repeated twice daily for 6 days When treatment was delayed for five hours after infection, the result was not as good as with immediate treatment, although some protection was still demonstrable

In these experiments we were able to isolate *Bact typhosum* from the heart blood, spleen, and, less often, the kidney of some apparently healthy mice one week after infection and treatment After one month a positive culture was obtained from the spleen of one of twelve mice examined, and serum tests sometimes showed the presence of agglutinins We also found that treated mice which survived seemed to possess slight active immunity to a second infecting dose one to four weeks later (This phenomenon has not been observed in experiments on the treatment of hæmolytic streptococcal infections in mice)

BACT PARATYPHOSUM

Bact paratyphosum A strains were not used since those available were of relatively low virulence

We tested two recently isolated, highly virulent *paratyphosum* B strains which Prof. Hedley Wright kindly sent us It was unnecessary to use mucin as 500 organisms killed 60, and sometimes 100, per cent of mice within 48 hours of infection Protection was obtained against 100 to 1000 fatal doses, when treatment with the drug was either a single dose given immediately after infection, or a similar dose repeated twice daily “ Delayed treatment ” was less effective than immediate treatment The majority of the deaths occurred before the third day of observation, irrespective of the method of treatment

BACT AERTRYCKE

Altogether six strains were used, three of which were isolated from guinea pigs, one from a mouse, and two from human subjects We are indebted to Prof W W C Topley for two of the strains, and to Dr F A Knott for one Suspensions in 5 per cent mucin of all the cultures were virulent for mice, and gave very similar results with treatment

A single dose of the sulphonamide produced a slight, but definite, retardation in the time of death. When administration of the drug was “ delayed for five hours ” after infection and repeated twice daily, the treated mice survived for only two to three days longer than the controls

The best effect was obtained with repeated doses of the sulphonamide (Table II), but even here the protection was only temporary Treatment produced delay in the time of death of mice infected with a large dose of culture (10,000 fatal doses), but the majority of these animals died within a few days of the controls Only some of the mice infected with approximately one fatal dose could be kept alive for twelve days

The *Bact aertrycke* survived for several days in treated mice although the mice appeared healthy, the blood, spleen, and gall bladder all gave a growth of the organism seven days after infection, and a positive culture was obtained from the spleen of one animal which had survived for eighteen days

TABLE II

Treatment of Mice Infected with Bact aertrycke (*with Mucin**)

Treatment with the sulphon amide	Approx number of organisms in infecting dose	Number of mice (out of groups of 10) dying on each day after infection							Mice surviving 12 days

	500 000				2	5	1	2	0

Ten mice injected with mucin alone and 10 mice injected with mucin and treated with the sulphonamide all survived.

FRIEDLÄNDER'S BACILLUS

One strain of exceptional virulence was selected from a series sent from the National Collection of Type Cultures through the courtesy of Dr St John Brooks A protocol of a typical experiment made with this strain is appended (Table III) The outstanding feature was that frequent doses of the sulphonamide gave temporary protection only Although, at an early stage of the experiment mice infected with 10 000 fatal doses appeared healthy it was only those animals which had received approximately one fatal dose which survived for twelve days.

TABLE III

Treatment of Mice Infected with Friedlander's Bacillus (Strain 12) (Without Mucin)

	100 000	1		9					0
	1,000 000	1	6	3					0

It is probable that the infection produced in mice by a number of other members of the genus bacterium may be influenced by the sulphonamide Since this paper was written, slight protection was obtained against a Gram negative slow lactose fermenting bacillus which was highly virulent for mice It was isolated by Dr David Haler from a case of adult dysentery but does not conform to any of the recognised features of the dysentery group. Dr Haler informs us that a similar organism is sometimes associated with pyelitis and with infantile dysentery

PNEUMOCOCCUS

It has already been reported (Buttle et al 1936) that the sulphonamide has little effect in the protection of mice against infections by the pneumococcus Type I In view of the effect obtained against other infections by repeating the doses of sulphonamide at short intervals experiments on the treatment of pneumococcal infections were resumed.

In the control series groups of 6 mice were killed within forty-eight hours by infecting doses of approximately 5 pneumococci Type I Groups of treated mice (40 mg twice daily) infected with 5 and 500 pneumococci appeared healthy for the first three days but some deaths were observed on the fourth day and by the twelfth day all the mice had died

The experiment was repeated with another virulent strain of pneumococcus Type II The time of death of the treated mice was delayed a little longer than in the case of the infection with the Type I strain.

Rosenthal (1937) studied the effect of the sulphonamide on mouse infections with a number of pneumococcal strains of Types I II and III He reported that 25 to 50 per cent of the treated mice survived for seven days and, in the case of one strain 86 to 100 per cent of mice were cured. The sulphonamide was injected subcutaneously in emulsion with olive oil. It is possible that strain variation may explain the difference between Rosenthal's results and ours, although another factor may have been the method of administration of the drug

PASTEURELLA

Preliminary work would suggest that the drug has a temporary and very slight beneficial effect against infections with *Past. pseudotuberculosis* and *Past septica*. Further experiments are projected in view of the relationship between these organisms and *Past. pestis* *

Effect of the Sulphonamide in vitro

Only three of the above organisms have been studied so far—viz *Bact aertrycke Bact typhosum* and pneumococcus

BACT AERTRYCKE

The inhibitory effect of *p*-aminobenzenesulphonamide on the rate of growth of this organism in culture medium in vitro is not nearly so great as that found with the streptococcus (Colebrook, Buttle and O'Meara 1936) An inoculum of approximately 8 organisms of our guinea pig strain G 620 grows in the broth medium described by Wright (1933) and the addition of 0·1 per cent. of the sulphonamide does not inhibit the growth appreciably (see also Nitti Bovet and Depierre 1937) If the tubes are incubated anaerobically however the addition of 0 1 per cent sulphonamide inhibits growth for sixteen hours.

If the organisms are grown in defibrinated human blood (G A H B) and incubated in slowly rotating tubes it is necessary to use an inoculum of 1 000 000 organisms in 0 5 c.cm of blood to obtain growth (an inoculum of 100 000 organisms is destroyed by the blood itself) The addition of 0·01 per cent of the sulphonamide to the blood produces a slight bactericidal effect 1 000 000 organisms are destroyed but there is no appreciable effect on an inoculum of 10 000 000 organisms. If the leucocytes are removed from the blood by the method described by Fleming (1926) *the addition of 0·01* per cent of the sulphonamide does not influence the growth of an inoculum of 1 000,000 organisms With streptococci on the other hand the addition of 0·01 per cent of the sulphonamide considerably delayed the growth of the cocci even in blood from which the leucocytes had been removed As the sulphonamide produces so little inhibition of growth of

---

* *Staphylococcus*.—Since this paper went to press we have tested for virulence a number of strains of staphylococci isolated from bovine and canine sources by Prof F C Minett One bovine strain was of exceptional virulence mice being killed within 48 hours by approximately 50 organisms suspended in mucin Treated mice that had received 1000 fatal doses survived for upwards of 12 days In our previous work with a large number of human strains we did not find any organisms of sufficient mouse-virulence to enable us to demonstrate any degree of protection

Bact aertrycke in culture medium or in deleucocyted blood it seems possible that, in whole blood, it may act by rendering the organisms more susceptible to phagocytosis (see also Long and Bliss 1937)

The effect of the sulphonamide on the growth of *Bact aertrycke* in vitro appeared to be so slight that experiments have been carried out to determine whether there was any other factor contributing towards the recovery of the treated mice

The serum taken from two treated mice seven days after infection did not agglutinate *Bact aertrycke* Treated mice which had survived for two weeks were just as susceptible as normal mice to a further injection of culture

In another experiment, a group of six mice was injected intraperitoneally with the soluble polysaccharide prepared by Prof Topley, from the mouse strain of *Bact aertrycke* and very kindly sent to us for the investigation, a second group of 6 mice, similarly injected with the polysaccharide was treated with the sulphonamide, and a third group received mixtures of the sulphonamide and the polysaccharide. The mice in the treated groups died at the same time as the controls which had not received the sulphonamide

BACT TYPHOSUM

The results of tests with this organism were similar to those obtained with *Bact aertrycke* In preliminary experiments the drug produced little inhibition of growth in broth, whereas a definite bactericidal action was demonstrable in defibrinated whole blood An inoculum of 100,000 organisms grew in normal blood, whereas in blood containing 0 04 per cent of the sulphonamide 1,000,000 organisms were killed, and 10,000,000 were inhibited for 18 hours

PNEUMOCOCCUS

Although the treatment of pneumococcal infections in the mouse is even less effective than the treatment of *Bact aertrycke* infections, the inhibition of growth of the pneumococcus, Type I, in a broth medium is nearly as great as that obtained with the hæmolytic streptococcus and very much greater than that with *Bact aertrycke* Thus, 0 01 per cent of the sulphonamide prevents the growth of 50 pneumococci in broth, while 0 1 per cent of the sulphonamide is almost without effect on the growth of a smaller inoculum of *Bact aertrycke* If, however, the pneumococci are grown in defibrinated human blood (G A H B), incubated in slowly rotating tubes, the effect of the sulphonamide is only very slight The cocci grow in twenty four hours from a very small inoculum—3 organisms—with or without the addition of 0 01 per cent of the sulphonamide, the growth in the blood containing the sulphonamide, however, is not as rapid as in the controls The results of experiments in vivo, therefore, correspond more closely with those obtained in vitro in blood than with those in culture medium

The above results of in vitro tests are of a preliminary nature, only one strain of each of these organisms having been tried with the blood of two individuals Further work is clearly necessary on the action of the sulphonamide on several strains of organisms in vitro in the blood of different individuals

Discussion

The foregoing experiments show that the early oral administration of *p* aminobenzenesulphonamide prevents or delays the development of septicæmia and death in mice infected with a number of different organisms An attempt has been made to summarise the available data in Table IV, earlier results with the hæmolytic streptococcus and meningococcus are included for purposes of comparison It is emphasised that the figures are only approximations and depend to some extent on the virulence of the organisms used

It will be seen that there are three grades of protection In the first group, intensive treatment with the drug merely delays the death of the mice, in the second, frequent doses are requisite if the protection is to be other than temporary, and, in the third, a single dose given immediately after infection produces a maximal effect

With regard to the rôle of the sulphonamide, evidence has been adduced that the drug has an inhibitory effect on the multiplication of small numbers of streptococci and various other organisms in vitro in broth medium and in deleucocyted blood It is almost certain that this also occurs in the blood in vivo, but it is probable that here the leucocytes also play a part Long and Bliss (1937) observed a marked degree of phagocytosis by the leucocytes in the peritoneal exudate of mice infected with hæmolytic streptococcus and treated with the sulphonamide, there was no evidence of phagocytosis in the untreated controls These authors therefore believe that the drug has an important action in injuring the organisms and making them more susceptible to phagocytosis In our experiments on *Bact aertrycke* and *Bact typhosum*, we obtained some support for this view, we could demonstrate a slight bactericidal effect for the sulphonamide in whole blood in vitro, but in deleucocyted blood or culture medium there did not appear to be a definite diminution in the rate of growth.

TABLE IV

Grades of Protection with p *Aminobenzenesulphonamide*

—		Approx number of fatal doses against which mice are protected	
		For 2 days	For 12 days
A Frequent doses give temporary protection only	*Bact aertrycke*	10 000	1
	Friedländer's bacillus	10 000	1
	Pneumococcus	100	0
	Past pseudo tuberculosis	100	0
	Past septica	100	0
B Frequent doses give lasting protection (Single dose gives temporary protection)	*Streptococcus hæmolyticus*	10 000	
C Single dose gives lasting protection	Meningococcus	1 000 000	
	Bact typhosum	*100–1000*	
	Bact para typhosum B	100–1000	

The drug is now being tried in the treatment of hæmolytic streptococcal and also in a few meningococcal infections in man, but the results of the mouse experiments would suggest that it might have an even wider application In certain infections, the action is probably insufficient to be of clinical value by itself, and, in these, the sulphonamide might possibly be useful in conjunction with other measures—*e.g.*, therapeutic serum in the treatment of pneumonia

Summary

p Aminobenzenesulphonamide protects mice against multiple lethal doses of *Bact typhosum* and *Bact paratyphosum* B There is some degree of protection against *Bact aertrycke*, Friedländer's bacillus, pneumococcus, *Past pseudotuberculosis*, and *Past septica*

A single dose of the sulphonamide gives lasting protection against some of these organisms, repeated doses lead only to delay in the death time of the mice infected with others

In no instance are the results of treatment as satisfactory as in hæmolytic streptococcal and meningococcal infections

THE EFFECT OF COMPRESSED-AIR BATHS UPON THE VITAL CAPACITY IN EMPHYSEMA

By G E Beaumont D M Oxon F R C P Lond.
PHYSICIAN TO THE MIDDLESEX HOSPITAL, LONDON AND TO THE BROMPTON HOSPITAL AND

J F Dow, M B Camb
LATE HOUSE PHYSICIAN TO THE BROMPTON HOSPITAL

The compressed air chamber as used in the Brompton Hospital was introduced into this country about fifty years ago and was originally employed in the treatment of almost any chest disease Soon its limited value was discovered and its range became narrowed In 1894 Dr Theodore Williams[1] reported on its use in chronic bronchitis with emphysema and in asthma Of the former disease he had treated 33 cases, of which 26 improved of the latter 15 cases, of which 12 improved. It was suggested in this paper that the results were due to an increase in lung capacity gained by the forcing open of alveoli previously out of use

It is obvious that a patient suffering from difficulty in oxygenating his blood, due either to insufficiency of normal alveolar epithelium or to the limitation of respiratory movements will benefit from an increase in the partial pressure of oxygen in the atmospheric air while this lasts The normal partial pressure of oxygen is 20 per cent of 760 mm of mercury (i.e 152 mm.) but in the compressed air chamber, where the pressure rises to a maximum of one and two thirds of atmospheric pressure the partial pressure of oxygen will correspondingly rise to 5/3 of 152 (i.e 257 mm. of mercury) and this may well explain the marked increase in comfort which an emphysematous patient experiences while actually in the bath. This effect is however essentially a temporary one and lasting benefit can result only if the respiratory excursions are amplified as the result of the increased pressure, or if some alveoli are brought into use which previously had been dormant by reason of spasm or occlusion

In order to test whether the compressed-air bath does bring into use previously dormant alveoli nine patients suffering from moderately severe emphysema were examined while undergoing this treatment and vital capacity estimations were made before and after treatment (see Table) The initial vital-capacity reading in each case was considerably below the calculated normal reading In addition each patient showed clinical and radiological evidence of generalised emphysema. The course of treatment under observation lasted about two months and each patient attended twice weekly At each treatment the pressure was increased gradually until it reached one and two thirds atmospheres at the end of half an hour This was maintained for one hour and during the last half hour the bath was gradually decompressed. In some of the cases under observation the respiratory rate was noticed to drop to nine or ten per minute

VITAL CAPACITY READINGS BEFORE AND AFTER TREATMENT

Vital capacity readings were taken at every third treatment before after and once during the compressed-air bath and are recorded in cubic centimetres. Patients received two compressed-air baths a week.

Results —Eight patients stated that while in the bath they experienced sensations described as comfort looseness, or freedom. Two patients considered that they were constantly less short of breath than they had been before the treatment was started (Nos. 1 and 6) One patient (No 3) felt no improvement at any time No definite temporary or lasting increase in the vital capacity was found On the occasion when the estimations were also made while the patients were in the compressed air bath no definite rise in the vital capacity was obtained except in the case of No 8 in whom the initial reading on that day was abnormally low

Conclusions —The estimation of the vital capacity of patients suffering from emphysema carried out before and after compressed air bath treatment does not support the view that any improvement in their condition is due to opening up of alveoli which previously were out of action

THE PHONOSTETHOGRAPH

A NEW METHOD OF RECORDING AND REPRODUCING SOUNDS HEARD ON AUSCULTATION

By C Vaughan Henriques, M R C S Eng

(From the Electrical Research Laboratory, King's College Hospital Medical School, London)

THE problem of recording normal and abnormal heart sounds for the purpose of reference and study has for many years occupied the attention of physiologists and clinicians Indeed, according to Hirschfelder, the first attempts were made by Donders as long ago as 1856 Most of this pioneer work was however chiefly connected with the photographic registration of the vibrations produced by the heart sounds conducted through the chest wall In this field the brilliant work of Hürthle, Einthoven, Geluk, Holowinski and Lewis and others stand out

With the evolution and rapid improvement of the thermionic valve and electrical amplifying systems came attempts by means of modern microphones to pick up the heart sounds through the chest wall and reproduce them through loud speakers The results obtained this way varied enormously in faithfulness, volume, and background noise Such noise chiefly resulted from the hiss caused by the type of microphone used, amplified frictional noises caused by the microphone rubbing against the skin, and contraction of the intercostal muscles The first worker to employ an electrical system of auscultation of the heart successfully was R C Cabot of Massachusetts in 1923 The details of this apparatus were published in 1924 by Gamble and Replogle

During the past year or so I have been experimenting with a new electrical technique and an instrument I have designed for the purpose of auscultating the heart and chest, and recording phonographically the clinical sounds present in health and disease This apparatus is called the phonostethograph The experiments have proved very successful and the apparatus has been standardised. The record takes the form of a phonographic disc which may be replayed hundreds of times These records may be interpolated where necessary with speech explanations of the cases under observation, and at the time of recording The time taken to make a record varied from five to fifteen minutes, and it can be replayed within thirty seconds In all about 200 cases have been recorded, including normal average subjects, athletes, cases of mitral stenosis, aortic stenosis, and congenital heart disease In these records the normal and abnormal sounds may be reproduce loudly and clearly or in the attenuated for as heard with the stethoscope In cases whe the rhythm of the heart is too fast for easy timin of murmurs, it is possible to produce slow motio records for detailed analysis The normal cases wer recorded before and after exertion, and it was interesting to note the delicate changes in sound frequencie which occur in the heart sounds of individual subject after exertion, changes which were undetectabl with the stethoscope The fœtal heart at 30 week has also been recorded

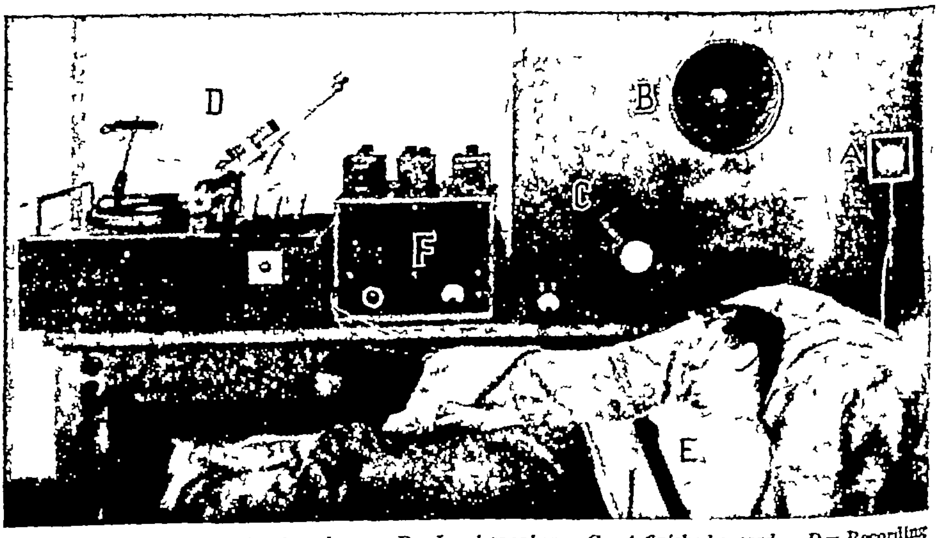
A great deal of time could be saved in teachin students to recognise various clinical abnorma sounds that occur in cardiac disease by giving the the opportunity of studying at leisure the characteristics of these cases that it is now possible t record faithfully in an amplified form In th manner after being accustomed to hear the abnorma sounds loudly and clearly reproduced they wil develop greater skill in the detection of these sounds and when confronted with the living patient the will know what to listen for, and will be able mor easily to detect any variations from the normal tha may be present In support of this argument cannot do better than quote the remarks of Cabo (1923) referring to the great advantages of electric amplification of heart and breath sounds for th purpose of clinical teaching and investigation —

> "The advantages of such an apparatus for teachin purposes are very great Chief amongst these is the simultaneous hearing of the identical sound by the instructo and students Immediate comment is possible, followe by the student's immediate attention to the feature commented on Another advantage is the economy of tim and strength for both patient and teacher"

Cabot was then referring to his electrical stethoscope introduced in 1923 and used with great succes in his clinic

THE INSTRUMENT AND ITS USE

The greatest problem which presented itself in the working out of a suitable technique that would ensure the production of good recordings was that of exclusion of interference by extraneous noise. A microphone chest-piece had to be devised which would give maximum sensitivity combined with a minimum of background hiss After experimenting



The apparatus A = Speech microphone B = Loud speaker C = A finished record D = Recording section E = Chest piece fixed to patient F = Amplifier with frequency filters above with several types of microphone it was decided to use a microphone of the carbon granule type. I devised one that embodied the necessary characteristics of lightness sensitivity and minimum hiss It was also found impracticable for the investigator to hold the microphone in position manually as the friction of his fingers against the microphone casing caused a great deal of noise which interfered with the clarity and quality of the recordings.

The phonostethograph consists of a high gain amplifier with four stages of amplification and fitted with frequency filters which enables the investigator to eliminate at will any group of sound frequencies that might interfere with the clinical sounds under observation. The recording section embodies a system of high fidelity direct recording especially constructed for this work by the Marguerite Sound System Company A moving-coil mains energised loud speaker and a pair of earphones are also incorporated in the circuit.

The technique employed is as follows —

The investigator finds the region over the heart or lung where the clinical sounds are best heard with a stethoscope Having found the spot it is marked with a skin pencil The chest-piece is then applied over the area by means of an elastic belt The necessary adjustments are made to the amplifier controls and the investigator listens in with the earphones When he has obtained the optimum degree of volume of the sounds under observation the loud-speaker is then brought into operation and the heart or breath sounds become audible loudly and clearly to all present Should it then be desired to make a permanent record of the case in question he sets the recording unit in operation and the record is made in a few minutes By means of the speech microphone he makes his personal observations on the case all of which are recorded permanently During the entire procedure the patient lies on a couch which is screened off from the apparatus

The records produced by the phonostethograph are "master discs and not ordinary gramophone records and should only be reproduced by means of a high class reproducing unit This is an important point since in order to study heart sounds in detail it is necessary to be able to hear as perfectly as possible the full range of sound frequencies generated by the heart's contraction and recorded on the master disc. Should a reproducing apparatus of inferior efficiency be used owing to inefficiency of the mechanism only a poor representation of the frequency range will be rendered audible

Compared with other methods of registering heart sounds the phonostethograph offers the great advantage of allowing the patient to breathe during the actual recording process without the record being masked by interfering breath sounds This is made possible by the use of special frequency attenuators by which these sounds can be cut out of the sound picture before it is recorded

ADVANTAGES

The phonostethograph should prove useful for teaching and for demonstrating typical cases of cardiac and pulmonary disease at clinical demonstrations and lectures with the minimum of fatigue to patients by avoiding several individual examinations It would also be useful in keeping records of cardiac cases for reference and study; and for following up the improvement or retrogression of these cases by comparing records taken at various times and under various conditions of treatment &c By the use of this technique the physician has no need to rely on his memory of the sound picture or the attempts at graphic description of sounds that only too often defy adequate description

I should like to take this opportunity of thanking Mr E M E Decottignies for his kind assistance and coöperation in the foregoing experiments

The apparatus and its recordings were demonstrated at a meeting of the Physiological Society held at Guy's Hospital on Dec. 12th The experiments were carried out in a laboratory kindly placed at my disposal by the authorities of King's College Hospital medical school.

ENCEPHALITIS IN MEASLES

REPORT OF FIVE CASES WITH ONE DEATH AND ONE RECOVERY AFTER CONVALESCENT MEASLES ENCEPHALITIS SERUM

By G A. E. Barnes M.R C S Eng
TEMPORARY ASSISTANT MEDICAL OFFICER

ASSISTANT MEDICAL OFFICER AND
M. Mitman M.D M.R C.P Lond. D.P H.
MEDICAL SUPERINTENDENT OF THE EASTERN (L.C.C.) HOSPITAL

More than 200 cases of encephalitis in measles have been reported. The number recorded has been greater in recent years probably because of the increasing recognition of this complication. In 1928 Ford gave an excellent summary of the cases recorded up to that time and produced a clinical classification of the types. A similar résumé has been made recently by Guibert (1930)

The complication occurs at all ages and apparently bears no relationship to the severity of the attack of measles. The time of onset is variable, but the end of the eruptive period between the 3rd and 7th day of the rash is the commonest Clinically the striking feature of the condition is its polymorphism but for practical purposes two main types may be distinguished. In the first there is evidence of a more or less profound and diffuse involvement of the nervous system—a meningo-encephalomyelitis. The various parts of the nervous system are, however affected in different degrees. As the condition evolves there is a tendency for the diffuse features to be replaced by localisation in one or more parts of the nervous system. This predominant localisation permits of the classification of the disease into its various clinical types: the meningitic the encephalitic the myelitic the multiple cerebral focal, the mental, the hemiplegic and aphasic the paraplegic the cerebellar or ataxic, &c. The initial general symptoms vary from a mild degree of apathy or irritability to a profound stupor or delirium Convulsions are common and may be severe; and general muscular rigidity is frequent. A great variety of nervous symptoms is revealed with returning consciousness In the other main group the initial diffuse symptoms are absent. The localised lesions may exist from the onset and may simulate a single focal lesion

The *cerebro spinal fluid* almost always shows some abnormality Generally the fluid is clear with some increase in pressure The slight or moderate increase in cells is due mainly to mononuclears. The protein content is also slightly or moderately increased If there is not a parallel rise in protein and cells the tendency is for the protein to be increased and the cells normal. The sugar content is uniformly normal or high, and the chlorides are normal or slightly diminished Bacteriological examination always gives a negative result Wide variations from these usual findings are, however, common in the recorded cases

On the *ætiology* of the condition two views are held. The commoner regards it as a specific encephalitis of measles, the other does not The most frequent histopathological finding is a perivascular myelin destruction suggesting a toxic rather than an inflammatory process The fatality rate is variously given as 10–25 per cent If the early dangerous period is passed the prognosis as to life is good, but permanent sequelæ are not uncommon

In *treatment* glucose, hexamine, sodium salicylate (intravenously and orally), and magnesium sulphate (orally, per rectum, intravenously, and intramuscularly) have been employed Convalescent measles serum has been used as a therapeutic measure Lowenburg and Schaller (1926) administered it intrathecally, intravenously, and intramuscularly, producing rapid improvement in the cerebro spinal fluid but with apparently little effect upon the clinical course Dufourt and Reure (1932) and Peterman and Fox (1933) also employed it but were not impressed with its value

ILLUSTRATIVE CASES

The five cases here recorded occurred during the measles epidemic in the first seven months of 1936 The points which appear of particular interest in this series are the frequency of meningeal signs and the diagnostic importance of involvement of the sphincter of the bladder One death occurred, and the post mortem findings are recorded. One case ran a course closely simulating epidemic encephalitis except that the stages of the disease evolved more rapidly This case was successfully treated by serum from a patient recovered from measles encephalitis No previous record of the employment of this particular type of serum can be traced in the literature

CASE 1—A very mild case of encephalitis in which the only symptom was retention of urine

A male aged 1 yr 7 mths

History—In patient of a general hospital since Jan 30th, 1936, for broncho pneumonia Feb 19th coryza conjunctivitis Feb 20th rash, first appearing on face

On admission (Feb 20th)—Temperature 97° F, pulse rate 132, respirations 40, severe attack of measles with gastro enteritis and broncho pneumonia

Progress—Gradual recovery from measles, broncho pneumonia, and enteritis but developed otitis media on Feb 25th On March 2nd all symptoms had subsided except that the stools were still loose Retention of urine with overflow, no abnormality in the urine Regular catheterisation began March 3rd seen by consulting surgeon who was unable to detect any surgical cause for the retention March 4th general condition good Knee jerks left present, right feeble Abdominal reflexes not elicited, pupillary reflexes sluggish, no meningeal signs March 6th radiogram of urinary tract negative Albuminuria, onset of cystitis March 30th began passing urine normally, cystitis rapidly improved April 22nd sent to convalescent hospital

The diagnosis of encephalitis was made in retrospect after the significance of retention of urine had been appreciated

CASE 2—A mild case in which the prominent features were meningeal signs and muscular weakness

A male aged 5 yrs 6 mths

History—April 8th 1936 cough, vomiting, nasal discharge, rash April 14th backache, pains in limbs and abdomen, shivering Retention of urine, constipation, weakness of legs

On admission (April 15th)—Temperature 98 2° F, pulse-rate 100, respirations 24 Thin, not very ill, general lassitude, fading morbilliform rash, slight bronchitis Cranial nerves normal, slight neck rigidity, no head retraction, slight positive Kernig on left, tendon reflexes not elicited except arm jerks, plantar responses flexor, right upper abdominal reflex present, others absent, general muscular weakness

Progress—April 16th lumbar puncture

Fluid clear under pressure	Protein 55 mg per 100 c.cm
Cells 6 per c mm	Globulin slight increase
Chlorides 770 mg per 100 c cm	Culture sterile

April 17th passed urine normally when sitting up, but unable to do so lying down Muscular weakness persists, particularly in muscles of back and legs, so that he could not walk or stand without support Neck rigidity passed off April 20th seen in consultation with Dr Macdonald Critchley who confirmed the diagnosis After this muscular power began to return and by April 27th he was able to walk by himself May 1st discharged mentally normal, muscular power apparently normal walking well, tendon reflexes present, but knee and ankle jerks sluggish No other abnormality in the central nervous system.

CASE 3—A severe case that succumbed Prominent features were the state of unconsciousness and the presence of meningeal and bladder signs

A female aged 3 yrs

History—May 8th, 1936 coryza and cough May 9th rash, which first appeared on the forehead May 10th drowsy, crying out, retention of urine May 12th much more drowsy, "sleeping" almost continuously, twitching of both arms, grinding of teeth, and rolling of the head May 13th passed urine for the first time since May 10th

On admission (May 13th)—Temperature 99 4° F, pulse rate 88, respirations 40 Measles staining of the skin Semi conscious, slight head retraction and neck rigidity bilateral positive Kernig sign, tendon jerks elicited but feeble, pupils failed to react to light, abdominal reflexes absent, plantar reflexes extensor, retention of urine with overflow

Lumbar puncture clear fluid under pressure Report (Dr W Mair)

Clear fluid	Chlorides 740 mg per 100 c.cm
Cells 20 per c mm (mononuclears)	Protein 90 mg per 100 c.cm
	Globulin increased

A *Staphylococcus albus* (contamination) was obtained from the first lumbar puncture the second was sterile

Progress—May 14th unconscious, tendon jerks absent, frequent twitchings of right arm and left side of face Continued in this state until death supervened on May 15th

Post mortem examination—We are indebted to Dr A B Bratton for the following summary of the necropsy carried out by him —

Microscopic foci of collapse in congested lungs Cloudy swelling of myocardium liver, and kidneys Slight excess of leucocytes in œdematous spleen Nodule of ectopic cortex in capsule of suprarenal body Congestion of pancreas Dilatation and congestion of urinary bladder No abnormality in stomach, intestines, uterus, or ovaries Middle ears clean

To the naked eye the brain spinal cord, and their meninges appeared congested Sections were taken from various parts of the cerebral cortex and white matter and from the basal ganglia mid brain, pons, medulla and cervical, thoracic and lumbar cord In all sections some degree of demyelination is present, for the most part this is inconspicuous, consisting of a few very narrow perivascular zones rather more frequent in the white matter than in the grey there is also a narrow subependymal zone over the left optic thalamus In the sixth thoracic segment however there is an area (0 1 by 0 05 cm) involving the central parts of both posterior columns astride the median raphe

In all sections perivascular 'cuffing' is also seen. The infiltration consists of lymphocytes, plasmacytoid cells, histiocytes, and rarely a few neutrophil leucocytes, and is usually sparse there being only a single row of cells, often incomplete but in the basal ganglia mid brain, pons and medulla there are occasionally as many as four rows Fat phagocytes also occur in the infiltration especially where there is a zone of demyelination around the affected vessel, and a few are present in other demyelinated areas There are also a few small hæmorrhages associated with the cuffing" The cuffed vessels are few and are situated more often in the white matter than in the grey but there appears to be no constant relation between the demyelination and cuffing: any one vessel may show both changes together or either separately

A demyelinating encephalitis is present in which the demyelination is less conspicuous and perivascular infiltration more conspicuous than usually described.

CASE 4—A mild case the prominent features of which were involuntary movements of the head and grimacing.

A female aged 1 yr 4 mths

History—June 11th 1936: cough coryza discharging eyes June 12th: rash which first appeared on face

On admission (June 12th)—Temperature 99 F pulse-rate 104 respirations 24 Typical attack of measles of moderate severity

Progress—June 17th symptoms of measles largely subsided Child irritable June 30th: temperature 105° F; attack of enteritis July 2nd involuntary movements of face and head grimacing; smiling at apparently nothing in particular as she appeared unaware of her environment; twitching of left side of face; head nodding and other purposeless movements. No evidence of tetany no meningeal signs Examination of central nervous system negative except that right knee-jerk was not elicited and left knee-jerk was feeble Still irritable July 4th parents visited the patient and thought she had a blank look and did not recognise them Movements continued rather intermittently Abdominal reflexes and tendon jerks not elicited Plantar responses doubtful July 5th: little more irritable Doubtful rigidity of neck. July 10th improving still grimacing but not so frequently Tendon reflexes still absent but abdominals now brisk and equal No meningeal signs Indefinite weakness of left leg Thereafter improvement continued slowly and after July 31st no movements were seen August 14th: apparently mentally normal; says "mummie and daddy" Stands by herself and walks around cot All tendon reflexes present but ankle jerks feeble; abdominal reflexes present and equal General condition good. August 20th: discharged.

CASE 5—A severe case successfully treated with convalescent measles-encephalitis serum The striking feature was the resemblance of the disease to epidemic encephalitis

A female aged 4 yrs 6 mths

History—July 5th 1936 cough July 6th: rhinorrhœa rash, which first appeared on the face July 9th: vomiting

On admission (July 10th)—Temperature 101 8 F pulse-rate 152 respirations 56 Quite ill; feverish and restless breathing distressed marked coryza; râles scattered over lungs; general morbilliform rash; Koplik spots in profusion

Progress—July 11th vacant look; slight internal squint; incontinence of urine; obstinate constipation; temperature subsiding July 12th: indefinite rigidity of neck; no retraction; Kernig sign not elicited deep jerks eye reflexes, and superficial reflexes present Screaming attacks particularly when disturbed does not talk refuses food; nasal feeding begun July 15th definite signs in the nervous system neck rigidity; positive Kernig; left knee jerk and both ankle-jerks absent abdominal reflexes absent; plantar reflexes doubtfully extensor; pupils equal react to light and accommodation vacant expression; doubtful weakness of the right side of face doubly incontinent; temperature rising

Lumbar puncture showed clear fluid under moderate pressure Report (Dr W Mair):

Appearance clear
Cells less than 3 per c.cm
Chlorides: 40 mg per 100 c cm
Protein: 40 mg per 100 c cm
Globulin: slight increase

Cultures: sterile
Wassermann and Kahn: negative
Colloidal gold 2 1000000

July 17th: much more lethargic almost unconscious All deep jerks and abdominal reflexes absent Temperature 100 F general condition much worse prognosis considered almost hopeless

Serum treatment—At this stage Dr W Gunn suggested the administration of serum from a patient convalescent from measles encephalitis 20 c cm were given intravenously and produced immediate benefit The downward progress was arrested and within 24 hours there was evidence of definite improvement Consciousness returned sufficiently to allow the patient to answer simple questions; the temperature began to subside she started taking fluids by mouth and the neurological signs improved July 19th: neck rigidity less pronounced; Kernig sign almost disappeared abdominal reflexes present left knee-jerk present drowsiness largely gone Thereafter her condition steadily improved and on July 22nd no abnormality could be detected in the central nervous system She was talking and feeding herself July 23rd a considerable change appeared in her demeanour She was "naughty screaming at the top of her voice constantly trying to get out of bed and tending to be vicious and destructive After one meal she threw her plate across the ward A fine tremor of the parkinsonian type appeared This changed manner persisted for a week during which time she slept badly and required hypnotics She then improved fairly rapidly and by August 2nd was apparently normal, tremor having disappeared She was discharged on August 22nd mentally normal, well behaved with normal speech regular action of the bowels and no abnormality of the central nervous system

DISCUSSION

Of the cases in this series all showed involvement of the sphincter of the bladder Definite meningeal signs were present in all except Cases 1 and 4 In Cases 3 4 and 5 mental symptoms or interference with consciousness occurred associated with involuntary muscular movements. Case 5 was striking in its resemblance to epidemic encephalitis and its rapid response to convalescent measles encephalitis serum was most encouraging

TUMOUR GROWTH IN HYPOPHYSEAL DWARFISM

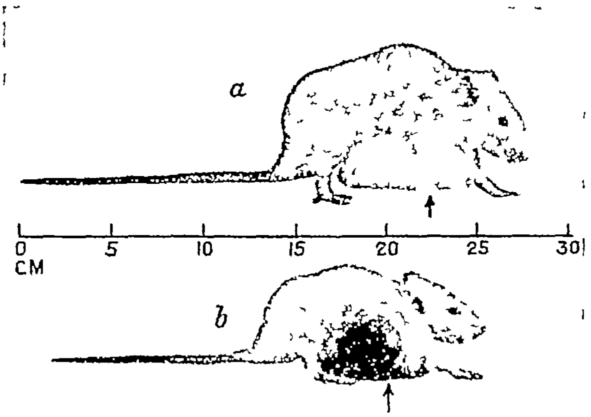
BY PROF BERNHARD ZONDEK, M.D

(*From the Gynæcological and Obstetrical Department of the Rothschild Hadassah Hospital Jerusalem*)

As reported in previous papers (Zondek 1936) it is possible to produce dwarfism experimentally in rats by the prolonged administration of follicular hormone which prevents the growth hormone elaborated in the anterior pituitary from entering the blood stream The absence of the growth hormone is shown by the fact that the rats will grow more slowly and cease growth earlier than normally While the control animals are 16 5 cm long and weigh 170 g on an average the dwarfs reach a length of only 14 4 cm and a weight of 90–100 g The slackening of growth is proportionate affecting equally all parts of the body—the head the bones the tail and the internal organs That the dwarfing is hypophyseal in origin may be deduced from the finding that Evans's pituitary growth hormone will stimulate the dwarf animals to grow again

TUMOURS IN DWARF RATS

It seemed interesting to investigate the development of malignant tumours in dwarf animals, since it has been suggested that this is influenced by the anterior pituitary Ball and Samuels (1932) observed a less pronounced growth of transplanted mammary carcinoma in hypophysectomised albino rats Reiss, Druckrey, and Hochwald (1933) have stated that if a rat weighing 60–120 g is inoculated with Jensen sarcoma two or three weeks after hypophysectomy, the tumour will grow to the size of a pea, or at most to that of a cherry, and will then undergo complete involution The greater the time since hypophysectomy, the shorter will be the duration of life for the tumour This effect is missed even if the slightest remnant of anterior pituitary tissue is left during the extirpation, which shows that it is the anterior lobe that inhibits the growth of the tumour This is also proved by the fact that the growth inhibition is counteracted by giving Evans's growth hormone



Eunuchoid dwarf rat (*b*) in which dwarfing was produced by 300,000 M U of dimenformon given from the age of one month and control rat (*a*) Both were males aged 6 months and are shown five weeks after the implantation of a benzpyrene sarcoma

If, therefore, the growth of malignant tumours depends upon the growth hormone of the anterior pituitary, one would expect that malignant tumours would not grow—or at least would grow much more slowly—in our hypophyseal dwarf rats than in the controls For the experimental tumour I used the benzpyrene sarcoma described by Kennaway and Cook et al (1935) I did not use, however, the primary tumours obtained by prolonged subcutaneous injection of benzpyrene, but those that had already gone through several passages on transplantation, all these tumours "took"[1]

For the first experiments a tumour material was used that had gone through six passages Pieces of the tumour, the size of a small pea were implanted into the left axilla of the rat As experimental animals we chose male rats that had each received twice a week 5000 M U (mouse units) of Dimenformon,[2] diluted in 0 2 c cm of oil, for at least five months They were typical dwarf males, 14 4 cm long and weighing 100 g The control animals were each injected over the same period twice a week with 0 2 c cm of olive oil They were 16 5 cm long and weighed 170 g After the tumour implantation the dwarf rats were further treated with dimenformon, the control animals still receiving olive oil

A tumour the size of a bean was palpable ten days after the implantation in both the control and the experimental animals The tumours grew rapidly, and three weeks after implantation they had already reached the size of a pigeon's egg At five weeks the tumours were enormous compared with the size of the rat, being about as big as a hen's egg The important fact is that the growth of the tumour was *just as rapid in the dwarf animals* as in the controls (see Figure)

Eight months later I carried out the same experiments in female animals, this time using a tumour material that had gone through twenty passages Here again the tumour "took" in every animal. The result was the same as in the first series The tumours grew extraordinarily rapidly and there was no difference between the controls and the dwarfs

These experiments prove that the growth of the tumour in hypophyseal dwarf animals is the same as in normal animals Although in the dwarf rats the growth hormone is out of action, and the growth of the body and of internal organs is accordingly inhibited, its absence does not seem to affect the development of implanted malignant tumours

There is, however, a characteristic difference between a hypophysectomised animal and our experimental animal. In the former, besides the growth hormone, all the hormones elaborated in the anterior lobe are absent In my experimental animals the growth hormone is probably being produced in the anterior lobe, but its secretion into the blood stream is being prevented. In my animals I block certain hormones, and among them the growth hormone Perhaps the hypophysectomised animal differs in its behaviour towards the tumour growth from one in which the pituitary is merely blocked by follicular hormone, and possibly my results, so contrary to those hitherto reported, may be explained by this difference This, however, does not seem to me to be very probable If, indeed, the growth hormone is one, or the only, stimulating factor in the growth of malignant tumours, one would expect that in our dwarf animals the malignant tumours would not grow at all, or would at least grow much more slowly than in the controls Since, however, the development of the tumours in our dwarf animals has not been inhibited at all, I do not believe that the anterior pituitary regulates the growth of malignant tumours

SUMMARY

1 Prolonged treatment with follicular hormone impairs the function of the growth hormone of the anterior pituitary, and hence results in hypophyseal dwarfism The release of the growth hormone into the blood stream is inhibited by follicular hormone, and this reduces the growth of the whole body, including the internal organs

2 When malignant tumours are implanted into hypophyseal dwarf rats—I used a sarcoma caused by benzpyrene which had gone through several passages—the tumours grow as fast in the dwarfs as in the control animals The absence of growth hormone in the dwarf rats consequently does not impede the growth of malignant tumours

3 From this it follows that the growth hormone of the anterior pituitary has no important effect upon the growth of malignant tumours

SOLITARY METASTASIS IN SPLEEN
IN CARCINOMA SIMPLEX OF RIGHT BREAST
WITH EXTENSIVE LOCAL SPREAD

By W H McMenemey D.M. Oxon.
M.R.C.P Lond D.P.M.

PATHOLOGIST TO THE NAPSBURY AND SHENLEY HOSPITALS ; HON ASSISTANT PATHOLOGIST TO THE WEST END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, LONDON

Although metastatic carcinoma of the spleen is by no means rare, it is unusual to find it in the absence of deposits in other abdominal viscera. The following case where the primary growth was in the right breast, is recorded because apart from local spread the only visceral metastasis was in the spleen.

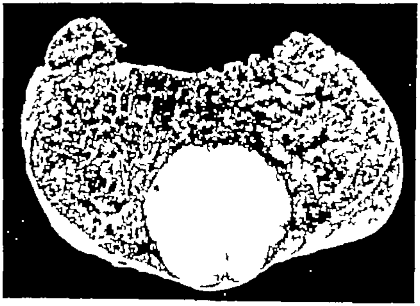
CASE REPORT

A female aged 66 was admitted to Napsbury Hospital on Sept 24th 1926 under certificate with the diagnosis of involutional melancholia She was depressed agitated, and distressed, refusing food and insisting that her bowels were blocked and would never act again The illness was gradual in onset without discoverable cause, and there had been no previous *symptoms* of mental disorder Physically she was ill nourished but no evidence of organic disease could be found Twenty years previously she had had an operation performed for a 'fibroid' uterus She had one son aged 37

During her stay in hospital she showed no change in her condition until March 10th 1936 when at the age of 76 it was noticed that she had swollen glands on the right side of the neck A few days later the left cervical lymph nodes were enlarged and the voice became husky Further examination revealed enlarged lymph nodes in the right supraclavicular region and axilla The right breast was fuller than the left and it contained a diffuse mass firm in consistency but not hard There was no anæmia On April 13th she complained of pain and tenderness over the right clavicle and of swelling of the right arm There were dilated veins over the clavicle and massive œdema of the arm with a temperature of 101 F Two days later she died

Autopsy—The body was that of an ill nourished elderly female of sparse build with massive œdema of the right arm Noticeable fullness of right breast the areola appearing to be pushed forward while the nipple was a little retracted Deposits of growth were visible in lines which could be felt as cord like structures radiating from the breast in all directions and particularly towards the clavicle On section the tumour was softer than the usual carcinoma and slightly pink in colour with a few punctate hæmorrhages It was adherent to the underlying muscle The cervical lymph nodes were greatly swollen and contained a softish pink growth undergoing necrosis in the centre The thyroid was enlarged and contained a deposit of growth on the right side and a smaller one on the left The larynx and trachea were not compressed The lungs pleuræ and bronchial lymph nodes were carefully searched for secondary tumours but no naked-eye deposits were found The heart was small and flabby and the great vessels showed only a little atheroma Examination of the abdominal cavity revealed one large metastasis in the spleen lying deep in the parenchyma towards the capsule and opposite the hilum There was a distinct bulge and stretching of the capsule of the spleen corresponding to the underlying tumour but at no point did they meet being separated always by a strip of splenic parenchyma The spleen weighed 205 grammes ; when cut longitudinally the tumour was found to be roughly spherical in shape with a diameter varying from 38 to 42 mm (see Figure) The gall bladder contained a few small stones. The uterus was small and atrophic The ovaries could not be identified (they were probably removed at operation) The peritoneum liver pancreas, kidneys suprarenals abdominal lymph nodes mesentery stomach and intestines were carefully searched but no other metastasis could be found The brain weighed 1120 grammes No secondary tumours could be found The spinal cord and skeleton were not examined for metastases

Histological appearances—Examination of the growth in the breast revealed a highly cellular and undifferentiated type of tumour the cells having scanty cytoplasm and varying considerably in size and shape with frequent mitotic figures The arrangement of the cells was so irregular that there was not even a suggestion of alveolar formation. There were numerous thin walled vascular channels, in the lumen of some of which could be seen tumour cells, together with red corpuscles but there was little in the way of stroma. Parts of the growth were seen invading the adjacent glandular and adipose tissues permeating between the cells of the latter and carrying with them thin walled vessels and scanty stroma Some chronic inflammatory reaction could be seen in outlying parts



The splenic metastasis.

The appearance of the growth in the spleen was similar to that of the one in the breast, except that there was closer packing of the malignant cells The advancing edge showed definite infiltration although in at least one part there was an appearance of pseudo-capsule formation. In one place there was a colony of malignant cells at some distance from the advancing edge Examination of parts of the spleen well removed from the tumour did not reveal any evidence of diffuse involvement with malignant cells. The spleen was of the senile type comparatively acellular with thickened trabeculæ and extensive hyaline change in the walls of the vessels

The histological appearances were considered to be those of a carcinoma simplex.

COMMENTARY

Carcinoma was until recently thought to metastasise to the spleen only very rarely Recent statistical inquiries however have shown that this is not the case and that splenic deposits are not infrequent Warren Shields and Davis (1934) for instance in a series of 1140 consecutive cases of carcinoma of all types found naked eye metastases in the spleen in 1 9 per cent. they occurred most frequently when the primary growth was in the lung (23 per cent of 13 cases) or in the breast (15 per cent of 193 cases) The variety of carcinoma which they found most frequently metastasised to the spleen was the rapidly growing and undifferentiated carcinoma simplex (of 102 cases of carcinoma simplex 20 had metastases in the spleen 18 of which had their origin in the breast) The growth presumably reaches the spleen by way of the blood stream because lymphatic vessels are said not to penetrate the parenchyma and they are infrequent in the capsule

It is, therefore, the relatively uncommon and undifferentiated varieties of carcinoma that may be expected to be found in distant organs and this is borne out by facts In this connexion, it is interesting to note that Krumbhaar (1926) found metastatic sarcoma to form a high proportion of spleen tumours In that they are soft rapidly growing tumours with a capacity for penetrating into the systemic and pulmonary circulations, sarcoma and carcinoma simplex may be considered very similar in their behaviour The more common type of carcinoma, for example the scirrhous, spreads by means of lymphatics and only rarely does it invade the blood stream and give rise to distant metastases (Sampson Handley) This then is one reason why secondary carcinoma of the spleen is uncommon.

Another factor appears to be the mobility of the spleen Kettle (1912) has suggested that, for this reason, tumour colonies are prevented from growing in the spleen, for it shares with other mobile structures —heart, striated muscle, and bowel—the distinction of being most rarely affected The age of this patient was 76 Possibly the interstitial changes which occur in senile spleens and consequent diminution of mobility account for the greater incidence of metastatic tumour in elderly as against younger persons

Warren Shields and Davis, however, noted that in every case where the spleen was involved there were also metastases in three or more organs In none was the spleen or spleen and lymphatic nodes affected alone The case described, therefore, is unusual in that the splenic tumour is the only abdominal metastasis and the only one which cannot be readily explained on the basis of a lymphatic spread.

The presence of this large growth in the spleen is further evidence against the view now partly discredited, but still upheld in part by Krumbhaar in 1927, that the spleen exerts a "specific antagonistic action" against carcinoma cells a view in favour of which there has been some experimental work.

SUMMARY AND CONCLUSIONS

1 A case is described of carcinoma simplex of the right breast with a large secondary deposit in the spleen No other abdominal metastases were found

2 In order for a carcinoma mammæ to metastasise to the spleen, a blood stream invasion is necessary This is most likely to occur with a carcinoma simplex

3 Granted a blood stream invasion, a splenic metastasis is most likely to grow when that organ is relatively immobile, as in the spleen of advancing years

4 The presence of a large metastasis in the spleen and none elsewhere in the abdominal cavity is further evidence against the now partly discredited view of a "specific antagonistic action" towards carcinoma cells on the part of the spleen

I wish to thank Dr A O'Neill, medical superintendent of Napsbury Hospital, for permission to publish this case

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF THERAPEUTICS AND PHARMACOLOGY

AT a meeting of this section held on Nov 9th, Dr D C HARE, the president in the chair, a joint contribution by Prof E C DODDS and Dr R L NOBLE on the relation between the

Pituitary and Gastric Secretion

was communicated by Dr Noble He described the severe hæmorrhagic lesions produced in the stomach of some animals after injection of posterior pituitary extract In the rabbit they could be produced unfailingly, and the typical appearances were seen in the upper area of the stomach, corresponding to the distribution of the oxyntic cells If the stomach contents were neutralised before the injection was given the effects did not occur In their experiments Prof Dodds and Dr Noble had collected specimens of gastric juice from cats and rabbits through gastric fistulæ which had usually been established before and allowed to heal completely The injection of the extract of the posterior lobe of the pituitary was found to inhibit the secretion of gastric juice induced by various stimuli. The most powerful stimulus to gastric secretion was that produced by injection of histamine, one milligramme producing in a rabbit a profuse flow after half an hour lasting about three hours The injection of posterior pituitary extract B P 15 minutes before histamine completely inhibited the secretion for even six or more hours The excretion of neutral red was similarly inhibited, if given with histamine it was usually excreted with the gastric juice after half an hour The secretions produced by sham feeding and pilocarpine were also inhibited by pituitary injection Control extracts of tissues other than the posterior pituitary did not affect the secretion, and the inhibition was only produced by the vasopressive principle and not by the oxytocic principle of the posterior lobe extracts In cats the response was the same whether the animal was unanæsthetised or under Nembutal. In searching for a more physiological stimulus than histamine the effect of insulin on gastric secretion had been observed A subcutaneous injection of two units in a cat caused a definite secretion which was not so profuse and was of shorter duration than that found after histamine The acid values were slightly lower Insulin, however, increased all components of the juice, and in contrast to histamine caused a marked increase in peptic activity All anæsthetics abolished that action of the insulin The response appeared to be initiated but not maintained by the hypoglycæmia, the fact that the gastric stimulation by insulin was abolished by section of the vagi or decerebration showed that the mechanism involved was nervous If the animal were given a previous injection of pituitary extract and then tested with insulin no secretory response occurred, and control tests showed that this inhibition was not due to the antagonistic action of insulin and pituitary extracts on the blood sugar

From these results Prof Dodds and Dr Noble had concluded that a substance contained in the vasopressive fraction of posterior pituitary extracts abolished all types of gastric secretion which might occur in a normal animal. The action was found to affect the volume of gastric juice and not primarily the acidity but intravenous injections might prevent the formation of any gastric juice and a temporary condition of achlorhydria might ensue

Prof. Dodds was anxious to know whether any other agent had been found to inhibit the secretion of gastric juice completely

Dr Lucy Wills wondered whether the effect obtained by pituitary was related to the reduced acidity found in hyperthyroidism and asked if any effects had been produced by giving thyroid extract.—Prof Dodds answered that he had obtained none in his experiments

Dr R D Lawrence asked whether the stimulation of secretion could be obtained with insulin apart from hypoglycæmia —Dr Noble said it had only occurred with hypoglycæmia

Liver and Yeast in Macrocytic Anæmias

Dr Lucy Wills then gave a communication entitled Extracts of Liver and Yeast their Varying Efficiency in the Treatment of Macrocytic Anæmias She explained that two macrocytic anæmias pernicious anæmia and tropical (or nutritional) macrocytic anæmia were cured by whole liver or crude liver extracts Certain yeast extracts were effective in curing the tropical anæmia but would only cure pernicious anæmia after admixture with normal gastric juice Castle s theory of the formation of the liver principle by the interaction of an extrinsic and intrinsic factor had been thought to explain the ætiology of these two anæmias There was much evidence to suggest that the tropical anæmia was a deficiency disease and there was no suggestion of faulty gastric function As Marmite (autolysed yeast) a rich source of the extrinsic factor was curative alone the deficiency in diet had been assumed to be the extrinsic factor The rhesus monkey when fed on a diet based on one in common use among sufferers from the tropical anæmia, developed a macrocytic anæmia thought to be the animal counterpart of the tropical disease These two diseases, in man and monkey differed from pernicious anæmia proper in showing no increase in the bilirubin content of the blood less conspicuous variability in the size of the cells, and the absence of natural remissions These differences were difficult to explain if the two conditions were due to a lack of the one and same liver principle but for lack of any evidence of any other factor Castle s theory had been accepted as affording the best working hypothesis

Dr Wills, with Mr P W Clutterbuck D Sc and Dr Barbara Evans (see The Lancet Feb 6th 1937 p 311) had studied the nutritional macrocytic anæmia in monkeys and cases of pernicious anæmia They had found that the anæmic animals responded well to treatment with either liver extract or crude yeast extracts but that the purified form of the liver factor Anahæmin which was curative in true pernicious anæmia was absolutely inactive even in enormous doses in the macrocytic anæmia of the monkeys Two fractions one soluble and the other insoluble in ammonium sulphate had been prepared from yeast filtrates and the liver extract Campolon The insoluble fraction from campolon which would have contained any anahæmin present had induced immediate remission in two cases of pernicious anæmia but was completely inactive in monkeys The same monkeys however had responded to administration of the soluble fraction Similarly anæmic monkeys had failed to respond to the insoluble fraction from the yeast extract but responded to treatment with the soluble fraction

There was some evidence that the e two factors were both necessary for hæmopoiesis in man and rhesus monkeys but that in the production and cure of the nutritional anæmia of the monkey the soluble fraction was mainly concerned. Its action in tropical macrocytic anæmia was being investigated.

DISCUSSION

Dr Hamilton Fairley said that the macrocytic anæmias played a large part in tropical practice. Three types were thought to exist, the tropical macrocytic anæmia the anæmia of tropical sprue, and an anæmia apparently associated with malarial infection this last was probably tropical macrocytic anæmia with malaria superimposed Tropical macrocytic anæmia had been thought to occur in India, Africa and China He had recently been investigating blackwater fever in Macedonia and had seen two cases of anæmia with malarial infection in a neighbouring ward, which he considered were probably macrocytic anæmia. If that were so that condition must be very common in the Balkans and right through Europe He asked Dr Wills about her experience with the anæmia in monkeys There was, he said a need for much more work on tropical anæmia

Prof F Pyman inquired the technique of separating the soluble and insoluble fractions from ammonium sulphate

Prof. L J Witts asked whether Dr Wills s soluble fraction was curative in pernicious anæmia

Dr Janet Vaughan said she preferred to use the less pure preparations of liver extract. Her experience was that she had had to give relatively more anahæmin than of the cruder extracts She considered that the preparation of anahæmin marked a great scientific advance but doubted whether it was of such help to therapy Jacobsen Fiske and Subbarow had isolated three principles from liver suggesting that the whole problem was more complicated than had been thought From that point of view anahæmin probably did not contain all the principles involved and the cruder extracts would be better to use

Prof Dodds asked whether the very pure preparations were excreted very rapidly He mentioned the greater effectiveness of œstrin in oily solution over that in crystalline form and wondered whether a parallel were to be found in pure liver preparations

Dr S W F Underhill said that theoretically the cruder preparations should act more slowly One c.cm. of anahæmin had been found to maintain cases of pernicious anæmia in good health when given at six or even eight weekly intervals There must therefore be some power of storage There was no satisfactory animal test for the potency of the cruder liver extracts The purer extract showed well marked constancy in melting point and rotation but there was no reliable chemical or physical test for the cruder extracts

Dr Wills in reply said that she too had had difficulty in keeping monkeys alive with a lower red cell count than three million. That level was sufficient for experimental purposes The results from the soluble fraction tried in one case of pernicious anæmia had been inconclusive She and Dr Clutterbuck had not yet prepared crystalline material from their fractions

---

Cumberland Infirmary Carlisle.—A scheme of extensions to cost about £10 000 was submitted at the annual meeting of this hospital Plans and estimates have been forwarded to the Commissioner for the Special Areas asking for an indication of the amount of grant forthcoming in view of the fact that a great deal of work will be brought to the infirmary from the distressed areas of the county

ALCOHOL AND THE MOTORIST

A MOCK TRIAL

THE Fellowship of Medicine staged an amusing and instructive Mock Trial in the Barnes Hall of the Royal Society of Medicine on March 11th

The judge was Mr W H Cartwright Sharp, K C, and the jury was a decidedly special one, for it contained, among other distinguished persons, three Members of Parliament, a professor of physiology, and a well known woman novelist

CASE FOR THE PROSECUTION

A Mr Samuel Johnson, a middle aged man with a genial and somewhat detached attitude to life, played with great spirit by Mr W W Anderson, was indicted for an infringement of the Road Traffic Act, 1930, s 15 being under the influence of drink to such an extent as to be incapable of properly controlling his motor car

Mr W A L Raeburn, counsel for the prosecution, after explaining the nature of the charge and the evidence, called Miss Gladys Smith, a "travelling advertisement for a firm of beauty specialists" She testified that, driving behind the defendant, she saw him fail to start at a green light, drive suddenly across the crossing on the succeeding amber light, and proceed quickly up the steep hill opposite, zig zagging from side to side, she followed him to where he had stopped his car on the off side of the road and found him leaning back in a semi conscious state

P C James Maclean (Mr Keith Attenborough) said that at 10 26 P M he had been summoned by Miss Smith and had found the defendant with his head resting on his arms across the steering wheel, had smelt alcohol in his breath and, suspecting him of being drunk, had taken him to the police station

Dr P B Spurgin, police surgeon, Blank Division, said that he saw the defendant at 10 53 P M The defendant did not get up when he came into the room but consented to be examined. He swayed gently from side to side, said that a policeman had brought him there on foot, and then corrected himself and stated that he had been driven to the station in a car He had been uncertain about the starting point and destination of his journey He was rather flushed and his skin was slightly moist, his eyelids were heavy, and his appearance was sleepy His tongue was slightly furred and his breath smelt of alcohol, but not strongly His pupils were rather dilated and their reaction to light very considerably delayed In trying to touch the tip of his nose he twice missed His knee jerks were exaggerated until he realised that they were being tested. He swayed on standing with the eyes shut and the feet toe to heel. His pulse was rather full and the rate was 126 to the minute Dr Spurgin had concluded that he was under the influence of alcohol to an extent which made him incapable of properly controlling his car, and had told him so, and that he could send for his own doctor if he wished

The defendant had sent for Dr T R Snelling, who had arrived at 11 15 P M and examined him in Dr Spurgin's presence Dr Snelling had taken two samples of blood in the usual pipettes and had handed one to Dr Spurgin

Mr Laurence Vine, who defended Mr Johnson, cross examined Dr Spurgin, who replied that he would not have certified Mr Johnson as drunk *in charge* under Section 40 of the Criminal Justice Act, 1925, but that he was under the influence of drink within the Road Traffic Act, 1930 He was not so drunk that he could not give a valid consent to the examination. Dr Spurgin agreed that every one of the clinical symptoms, individually, might be due to other causes, and agreed with the finding of the special committee of the British Medical Association that there was no single symptom due to the consumption of alcoholic liquor which might not also be *assigned to some other pathological condition* He had not asked the defendant if he suffered from any other condition, though it was usually his practice to do so, and he would have done so to a private patient If the defendant had taken a dose of insulin two or three hours before the reaction would not necessarily be still apparent, and the symptoms could not have been caused by a dose of insulin *taken even an hour before* A diabetic, even though he had taken nothing to drink, could show these symptoms, except the sluggish reaction to light, for this was a particularly important pathognomonic sign of alcoholism In an alcoholic patient the pupils contracted under light but took a long time to dilate again when the stimulus was removed A diabetic might have a perfectly normal reaction Moreover, the diabetic usually *had a dry, red tongue* Furring of the tongue might, however, be caused by gastric disturbance, and failure to touch the tip of the nose by any one of several conditions He agreed that Mr Johnson's was a borderline case A disorder of general health was a possible explanation of the clinical picture He could not make any attempt to apportion the symptoms between alcohol and other causes

Dr H K V Soltau, expert for the prosecution, said that he had done the Widmark test on a sample of the defendant's blood He had devoted himself to this test for two years and had done several hundred estimations Relating the results to physical conditions, he said that when the blood content was below 80 mg per 100 g, most authorities agreed that the person was not intoxicated, but if the content was higher his performance of psychological tests and his control of a car in a difficult situation might be affected With a content of above 100 mg per 100 g a normal man was not capable of controlling a car Men who could drink an abnormal quantity of alcohol were usually found not to have a very high blood alcohol content A man who showed 130 mg would not be fit to meet an emergency The present specimen had contained 150 mg

In cross examination by Mr Vine, he said he would convict any man on a reading of 150 mg without any clinical tests or other evidence He admitted that acetone gave the same reaction as alcohol and might account for 25 mg in the estimation Assuming the alcoholic content to be only 125 mg, he had never yet met a man who was *not affected* by that amount A recent anæsthetic could have raised the apparent blood alcohol but not by more than 10 mg

Re examined by Mr Raeburn, he said that the highest acetone content likely to be found in a diabetic pursuing his ordinary life was 25 mg, and that 35 mg was the ordinary maximum for a non comatose patient The peak of the blood alcohol content was reached between *half an hour and one and a half hours* after drinking, and sooner if food had been taken The content declined at the rate of 20 mg per hour

This concluded the case for the prosecution, and after Mr Vine had submitted, unsuccessfully, that there was no evidence to go to the jury, he placed the defendant in the box

CASE FOR THE DEFENDANT

Mr Johnson said he was a commercial traveller He did not remember having any difficulty in controlling his car he had not zigzagged particularly; he had not swayed more than the policeman had he had not stood up when the police-surgeon had come into the room because he was a Communist. He had not been interested in the tests He suffered from diabetes and had taken a dose of insulin at about 7 o clock. He had not told the police-surgeon this Cross-examined he said that he had taken a pint and a half of beer the last glass being about 7 o clock He had only had a sandwich or two and had left the public house at 8 o clock A tooth had started to ache violently and he had gone to a dentist and had it out at 9 30 P.M. after the gum had been sprayed with ethyl chloride. He had taken no alcohol afterwards

Dr Snelling giving evidence for the defence said that the defendant was his patient and was a diabetic. On examination at the police station he had walked well his pupils were dilated and reacted slowly to light he answered questions steadily and sensibly picked up coins accurately and counted them correctly His speech was normal, face flushed knee-jerks normal he could touch the tip of his nose at the second attempt His pulse rate was 90 Dr Snelling had concluded he was suffering from an overdose of insulin but was fit to drive Cross examined by Mr Raeburn Dr Snelling said that the effect of insulin would not have worn off by 7 30 P.M. but that it would take four hours to reach its peak effect. The maximum overdose short of one producing collapse, after a few sandwiches and three glasses of beer would be between 25 and 30 units

Re-examined he agreed with the words of Conybeare on Diabetes and Insulin p 45 that hypoglycæmic reactions were most likely to take place between 2 and 4 hours after the injection of insulin but were sometimes strangely delayed. In answer to the judge, he said that the abnormal reaction to light might have been due to insulin

Sir James Purves-Stewart said that many of the symptoms were consistent with alcohol poisoning but that every one of them might be due to other conditions, such as emotional shock excitement on being taken to a police station exhaustion belladonna poisoning and carbon monoxide poisoning An overdose of insulin could produce all the defendant s symptoms A patient with over 400 mg of blood alcohol per 100 g would be comatose over 350 mg. stuporous; over 200 mg. hopelessly drunk With a content of 180 mg 80 per cent of persons showed moderate intoxication and 20 per cent. no signs with over 160 mg. 60 per cent of persons showed signs of intoxication and with 100 mg. only 33 per cent Fallacies of the Widmark test were that other volatile bodies—e g acetone—gave the same reaction as alcohol up to 20 or 30 mg Insulin poisoning was common in a patient who had not taken a proper meal. The Widmark test was inconclusive in this case Cross-examined he said that the effects of insulin in the present case would be apparent at 10 30 P.M. Insulin prevented the formation of more acetone but would not reduce the existing content Three glasses of beer taken at 7 P.M could account for a blood alcohol content of 150 mg at 10 30 P.M

Re-examined he agreed that acetone exaggerated the value of the alcohol in the test

ADDRESSES TO THE JURY: ACQUITTAL

Counsel then addressed the jury Mr Vine submitted strongly that they could not convict on the evidence of a test which was so compromised by fallacies and that, as this was admittedly a border line case the defendant must have the benefit of the very substantial doubt. Mr Raeburn pointed out that there was no evidence of the amount of insulin the defendant had taken and consequently no evidence of an overdose It was absurd to say that three glasses of beer would have caused such a high blood-alcohol the defendant must have drunk more liquor during the evening The judge summed up strongly in the prisoner s favour and the jury acquitted him.

The trial showed signs of careful preparation and fully illustrated the point which the Fellowship desired to make the ambiguity introduced into evidence based on the Widmark test when the defendant is a diabetic and has recently taken insulin without an adequate supply of carbohydrate, or has recently had an anæsthetic

LEAGUE OF NATIONS AND NUTRITION

AT the Lister Institute on March 10th Prof E J Bigwood of the faculty of medicine University of Brussels and Dr Hazel Stiebeling senior food economist Bureau of Home Economics U S Department of Agriculture spoke on two aspects of the nutritional work carried out in connexion with the health section of the League of Nations

Dr BIGWOOD described the work of the conference of experts meeting in Geneva last December to discuss methods of assessing the nutritional state of children and adolescents The difficulty was stressed of finding objective tests, other than simple physical measurements of which the value was very limited. These, which include height and weight in relation to age and sex physical appearance (slender medium or stocky type) firmness and elasticity of skin state of teeth state of muscles and signs of abnormal fatigue were however considered useful methods for study of large numbers of children and for periodical examinations It was recommended that small groups of children should undergo a more elaborate examination which should include inquiries into the diet family history a complete medical examination special tests of blood for hæmoglobin and protein-content together with some of the tests recently devised to reveal slight and incipient stages of vitamin deficiency Such were: for vitamin A deficiency the dysadaptation test (visual acuity in semi-darkness) for vitamin C vascular fragility and ascorbic acid saturation tests, and for vitamin D X ray examination of epiphyses of bones and phosphatase content of the blood. Dr Bigwood described with lantern photographs the posture test of Prof. Schiotz of Oslo by which it is claimed that slighter grades of malnutrition are revealed by the lines and contours shown by the musculature of the back

Figures were given of the results of some of these tests, as carried out in the elementary schools of Belgium Examinations of this type must he said at present be regarded as a subject for research rather than as routine methods but it is hoped, as a result of more widespread examinations and of correlation of the results obtained in different countries by these methods with those obtained from physical examination that more satisfactory objective criteria for the state of nutrition might be established.

Dr STIEBELING spoke of the conference of representatives of National Nutrition Committees held at Geneva in February, which she had attended as the United States representative. The aim of the council of the League in calling this conference was to collect information about the status and composition of such committees in the different countries, and about the work done and methods employed "to determine the state of nutrition of the national population and to spread the principles of improved nutrition among the population." Dr. Stiebeling described the extensive and well controlled nutritional investigations which had been initiated by the U.S. federal government. It was expected that these studies when complete would yield information of the total national consumption of the various foodstuffs in feeding of farm animals and in human dietaries, and of both qualitative and quantitative composition of the average diets consumed in the different income groups in the different States. Few results, she said, are yet available from this inquiry which is both laborious and costly, and will extend over several years. The importance of such work, carried out on an adequately large scale, cannot be over estimated, and the example set might with advantage be imitated by European countries.

REVIEWS AND NOTICES OF BOOKS

A Manual of Pharmacology

Eighth edition. By the late WALTER DIXON, M.D., B.Sc., F.R.S., sometime Professor of Materia Medica and Pharmacology, King's College, London. Revised by W. A. M. SMART, M.B., B.Sc., M.R.C.S., Lecturer in Pharmacology and Toxicology, London Hospital Medical College. London: Edward Arnold and Co. 1936. Pp. 483. 18*s*.

THIS text book was not the least of Dixon's many contributions to science in general, and to medicine in particular. It was last revised in 1929, two years before the author's death, and the rapid advance of knowledge in pharmacology has rendered further revision essential.

Dixon's book had certain characteristic features. It was dogmatic in its teaching and on controversial topics gave as a rule only the author's point of view. It contained a large number of illustrative tracings obtained in his laboratory, which fortunately have been retained in the new edition, and it tended to emphasise the scientific bases rather than the therapeutic applications of the subject. More systematic discussion of therapeutics has now been supplied, but the allocation of space does not always correspond with the importance of the subject. Another change is the inclusion of a large number of structural chemical formulæ. The book is, in fact, more complete in this respect than any other of comparable size, and for this reason alone is worth a place on the shelf of the pharmacologist or the chemist. The medical student, however, may feel with some justification that the amount of space devoted to formulæ is often disproportionate to that devoted to the actions and uses of the drugs they represent. The same lack of balance is evident in the amount of information given about different drugs. Thus twenty pages are devoted to aconitine, veratrine and the nicotine, coniine and curare groups of drugs—substances of pharmacological rather than therapeutic interest; and only twelve pages to the vitamins, the hormones (including pituitary, thyroid, parathyroid, suprarenal and liver extracts and adrenaline, insulin and ephedrine), vaccines, and sera. The use of liver and stomach extracts in macrocytic anæmias, perhaps the most striking therapeutic advance of the last decade, is dismissed in ten lines, while discussion of the cyanides fills six pages. This disproportion is the weakest feature of the present edition.

A commendable innovation is the introduction of several prescriptions, but unfortunately these are not always happily chosen. Sodium, potassium, and ammonium bromides have an identical pharmacological action, and a mixture of the three, as in mist. bromid. co. (p. 48) merely adds to dispensing costs without corresponding advantage. Of heroin it is rightly stated in the text that "its use might be forbidden without harming a single genuine patient," and yet a linctus containing heroin is included in the prescriptions. Guy's pill (p. 422) is little used to day, not because it is inert, but because the dose of digitalis is more conveniently adjusted independently of other drugs, and also because the organic mercurial preparations have largely replaced inorganic mercury as diuretics in cardiac disease. It is, of course, easy to criticise time honoured prescriptions in this way, but it is surely not the place of the pharmacologist to perpetuate those which, as a result of recent research, are being discarded by modern physicians. The author expresses in his preface a decided preference for the metric system of dosage, and yet in the prescriptions, and indeed throughout the text, the Imperial system is used almost exclusively.

The book has been brought up to date in several important respects, as by reclassifying drugs acting on cholinergic nerve endings (although few would include histamine among these), and by describing newly introduced substances such as ergometrine, mandelic acid, yatren, and cyclopropane.

Pneumonia

Diagnosis and Treatment. By CAMPBELL P. HOWARD, B.A., M.D., C.M., F.R.C.P. & S. Can., late Professor of Medicine, McGill University, and Physician to the Montreal General Hospital. London: Humphrey Milford, Oxford University Press. 1937. Pp. 373. 31*s*. 6*d*.

THIS book is written rather in the Germanic fashion. The wealth of data is well summarised, but a general lack of critical analysis and correlation of recorded work gives the impression that the author has not himself actively participated in the recent advances in diagnosis and treatment of pneumonia. The inclusion of 340 references accurately quoted in the 235 pages devoted to lobar pneumonia indicates, however, that he has read widely, although British work receives scant attention. Griffith's pioneer work on mutation of pneumococcus types, for example, is not mentioned, while there is no reference to the report to the therapeutics trial committee of the Medical Research Council on the serum treatment of lobar pneumonia.

After a historical introduction, succeeding chapters deal with infection and immunity, morbid anatomy, symptomatology, physical signs, complications, diagnosis, prognosis, and treatment of lobar pneumonia. There are numerous statements throughout the text which are at variance with current practice and belief—e.g., p. 24, "in most clinics at the present day Blake's precipitin mouse method is the one employed"; p. 30, "carriers of fixed types are rather frequent among the population at large"; p. 33, "all are agreed that the virulence of the pneumococcus varies greatly from year to year." In the chapter on treatment the indications for and against serum therapy might have been marshalled together with the methods for rapid pneumococcus typing The two concluding chapters deal with broncho pneumonia and the common cold the last one being perhaps the best in the book

Textbook of Medicine

Third edition By Various Authors Edited by J J CONYBEARE, M.C M D Oxon F R C P Physician to Guy's Hospital London Edinburgh: E and S Livingstone 1936 Pp 1027 21s

Conybeare's text book, which includes contributions by physicians from five of the London teaching hospitals and from places as far separated as Lucknow Johannesburg and Toronto has now completed its second four year cycle It is a middle weight among medical text-books offering the essentials of medicine within as small a compass and at as low a price as possible The teaching is clear concise and sound, and compression has not been applied to the extent of producing serious distortion. The new contributors in the third edition are Dr P M F Bishop clinical endocrinologist at Guy's Hospital, and Dr W D W Brooks of St Mary's who collaborates in the section on diseases of the chest Much rewriting has been done by the other authors including a complete recasting of the renal diseases section by Dr A A. Osman who now follows Fishberg fairly closely A short section on common skin diseases, doubtless in order to keep the price of the work low is entirely unillustrated We have no quarrel with its quality but it seems a pity to try to teach dermatology without pictures and we doubt whether the fundamental unity of dermatology with general medicine will be made evident to the student by these fifty pages It is difficult enough in the present state of our knowledge to display this unity even to those of greater experience! Perhaps here condensation has gone a trifle too far but that is minor criticism of a very serviceable book.

Frigidity in Women

Its Characteristics and Treatment By Dr EDUARD HITSCHMANN Director of the Psycho-analytic Clinic in Vienna and Dr EDMUND BERGLER, Assistant Director of the Clinic Authorised translation by POLLY LEEDS WEIL. New York: Nervous and Mental Disease Publishing Company 1936 Pp 76 $2

THE appointments held by the authors of this work entitle their views to respect Their thesis is the psychical nature of frigidity which they regard as a pathological inhibition not only preventable but curable In successive chapters they describe the development of female sexuality the characteristics of the female sexual life, the symptomatology degrees and types of frigidity; an account is given of two patients to illustrate success following treatment by psycho analysis and lastly we are told how frigidity may be prevented and treated

Upon the reader untrained in the technique of psycho-analysis and unfamiliar with its basic theoretical propositions, this book will make a complex impression He will recognise from the descriptions many female types and feminine reactions with which he is familiar; and despite the absence of any numerical records of successful cases, he will be impressed by the cures which the authors seem to have effected. At the same time he will find it difficult to accept the generalisations on the normal course of female sexual development upon which are based the diagnosis and treatment here described The average reader if he is not staggered with incredulity will regard the circumstantial account of penis envy as a normal phenomenon subject to what, in another context Prof. Whitehead has described as the fallacy of misplaced concreteness For descriptive convenience the concrete term is admittedly always preferable to the abstract If a little girl hates being a little girl, likes to dress and appear as a little boy and adopts an aggressive masculine attitude to the world it is perhaps more convenient to describe her attitude by the term penis envy than by other less concrete terms In some cases however the concreteness of the language, which is always disturbing to established ideas, appears to be inspired by a seemingly infantile desire to shock. It is tempting to administer to mulishly hostile and indignant critics outraged in their conventional ideas further shocks Among other pleasing consequences is the prospect of their powers of invective being eventually reduced to impotent inarticulateness.

Though indifferently translated this book may be read with profit by the larger circle of physicians to whom it is intended to appeal if they are willing to make allowances of the kind described.

Recent Advances in Anæsthesia and Analgesia

Second edition. By C LANGTON HEWER, M.B D.A. Anæsthetist and Demonstrator of Anæsthetics St Bartholomew's Hospital. London J and A Churchill Ltd. 1937 Pp 284. 15s

THERE has been considerable progress in the practice of anæsthetics during the five years since the first appearance of this book and to bring it up to date Dr Hewer has had to add eighty five pages even after he has discarded matter now obsolete. The newest agents, cyclopropane, divinyl ether and pentothal sodium are fully discussed as are also the interesting possibilities of electric anæsthesia A chapter each is devoted to thyroid and thoracic surgery subjects on which Dr Hewer can write with the authority lent by special experience Besides a chapter on carbon dioxide, which was to be expected the author has added one on oxygen therapy The fact that the anæsthetist's help is seldom requisitioned in this country for the purpose of oxygen administration far from making this chapter unnecessary or inappropriate suggests rather that his familiarity with the kind of apparatus used might make him a useful arbiter when methods are being debated. The book as a whole is well compiled and produced and will make an appeal to the senior student as well as to the specialist

Pediatric Nursing

By JOHN ZAHORSKY A B M.D F.A C.P Professor of Pediatrics, St Louis University School of Medicine. Assisted by BERYL E HAMILTON, R N Graduate of St Luke's Hospital St Louis London Henry Kimpton 1936 Pp 568 16s

THIS is an ambitious work and the first reaction of many medical practitioners to a study of its contents will be a fervent prayer that they may never have to work with a nurse who is fully conversant with its contents—her superior knowledge would be unbearable A closer inspection reveals that the details given in the earlier parts of the book under the general title of The Science are included so that the nurse may better understand the why and wherefore of the procedures described in the second part dealing with "The Practice" This latter is the more valuable part of the book, and novel chapters are included dealing with the organisation of a pædiatric department and of the nursery and with "the home and the family," a part of the world often forgotten by the hospital nurse The details on feeding have the usual disadvantage for British readers of being based on comparatively unfamiliar material, but English readers will note with satisfaction that the illustrations of typical stools are from specimens passed in Great Britain.

Birch's Management

And Medical Treatment of Children in India and the Tropics Eighth edition By Lieut Col E H Vere Hodge, B.A, M D Cantab, M R C P Lond., Professor of Medicine and Lecturer on the Diseases of Children, Medical College of Bengal, Calcutta, and First Physician to the Medical College Hospitals Calcutta Thacker, Spink and Co (1933), Ltd. 1936 Pp 377 Rs 7/8

Very few medical text books can have stood the vicissitudes of over ninety years, and though "Birch's Management" has passed through several hands since it first saw the light as a small, privately printed pamphlet in 1844, it has managed to retain much of its original character It is directed primarily to all those who have charge and care of children in the tropics, and who are out of reach of immediate specialist advice It follows that much of its content is concerned with general pædiatrics rather than with tropical medicine, and that the author has had to cater both for the intelligent layman and for the practitioner who has no special training in children's diseases A sensible compromise has been effected by marking certain of the more technical sections as being intended for practitioners, and by defining a number of common medical terms in the text With the exception of one or two slips (e g, that the tumour in pyloric stenosis will be found high up on the left side), the book is clearly written, reliable, and well balanced It is easy to appreciate what a stand by it must have proved to generations of parents, missionaries, and nurses

A Text-book of Medical Bacteriology

By R W Fairbrother, D Sc, M D, M R C P, Lecturer in Bacteriology, University of Manchester London William Heinemann (Medical Books) Ltd. 1937 Pp 437 15s

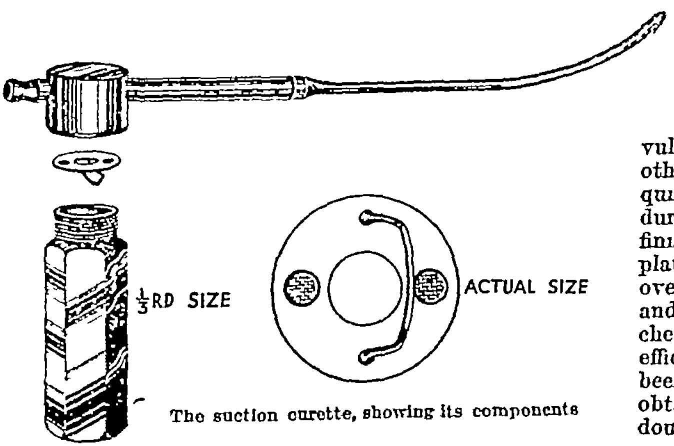
This short text book of bacteriology is likely to become popular with medical students because, though written on conventional lines, it is a clear, up to date, and readable account of those parts of the subject on which questions are asked at qualifying examinations The author has been wise to relieve his text of much of the technical detail which makes many otherwise good bacteriological manuals difficult for the student There are practical classes in which he should learn technique, and if he does not make use of this opportunity it is not likely that he can make good the deficiency from books As in nearly every other elementary text book of bacteriology there are too many subjects nibbled at, but not bitten into The paragraphs on some of the rarer infections are too short to be informative, and surely the mention of such obscure principles as the Forssman antibodies, leukins, and plakins is out of place in a book for elementary students

NEW INVENTIONS

COMBINED DIAGNOSTIC SUCTION CURETTE AND UTERINE SOUND

One of the greatest difficulties experienced during two years research work with œstrin at the Royal Infirmary, Bristol, was to get curettings on a definite day of the cycle To overcome this difficulty I designed a suction curette and collecting bottle, the use of which simplifies the technique so much that now patients can be curetted at a moment's notice in the out-patient clinic, and a specimen of endometrium taken with ease under nitrous oxide for unmarried girls, and 1 per cent novocain locally for married women

The instrument has a blunt, tapered sound like tip 5 5 mm in diameter, with an anterior and posterior cutting edge of stainless steel brazed to a malleable copper tube 4 25 mm in diameter and 6½ in long, with an anteroposterior eye just behind the cutting edge The malleability varies, being soft near the cutting edge and hard at its junction with a wider tube to which it is joined by a screw thread with milled nut The wider tube leads straight to the collecting bottle of brass (which is fitted as a pistol grip for the instrument) Suction is applied to an outlet in the same line as the tube, and this is obtained from a water suction pump The collecting bottle is fitted with a small trap which prevents any endometrium being sucked over even if the bottle is overflowing with blood, or with saline sucked in through the eye to wash through all the particles A suitable expanding speculum and a one toothed vulsellum are the only other instruments required for the procedure This instrument, finished in chromium plating, is compact—over all length 10¾ in. and handle 4½ in.—cheap, easy to use and efficient, and it has been useful also in obtaining curettings in doubtful cases of uterine growths



The suction curette, showing its components

I am indebted to Mr H L Shepherd for his encouragement and coöperation. The instrument was made for me by Messrs Ferris and Co, of Union street, Bristol.

G L Foss, B Chir Camb,
Clinical Assistant to the Gynæcological Out patient Department, Bristol Royal Infirmary and Colston Research Fellow

THE LANCET

LONDON SATURDAY MARCH 20 1937

THE ' EFFICIENCY ENGINEER

In many modern industrial processes human activities have become almost mechanical—a series of actions to be repeated thousands of times during the working spell If the human being be regarded solely from the mechanical aspect the total amount of the working day can thus be reduced to units of performance of the same task which can be timed Then if a normal timing can be found which takes into account the longer time taken by the slower workers to perform their units a rate of performance for each unit of work can be arrived at to which the slowest worker might be expected to work without undue physical or mental stress The faster workers who can exceed the average and do more units of work in a fixed time have an increased power of output which they can and do sell willingly to management and for which employers are prepared to bid There are various systems of this sort now on trial of which the Bedaux system is an example

Systems of payment by piece rates are not new It has long been recognised as fair that capacity to work easier and better than the ruck should be rewarded but piece rate payments based on time motion study are comparatively modern though time motion study itself is no new thing It dates from the days of Taylorism and the time motion studies of industrial physiologists or psychologists have done a great deal towards economising effort much to the advantage of employees in increased contentment and efficiency When the efficiency engineer however began to gain a footing in industry and the figures on which he estimated the length of time in which a particular piece of work should be done were accepted by management and piece rates based on them there was at first considerable protest from trades unions There is always a danger of speeding up if extra payment for performance above a certain standard is the chief incentive to work especially if the time of performance of each unit and the standard to be reached before extra payment is earned are fixed too arbitrarily The danger is the interference with the ordered working of the whole organism and whilst there is no reason to believe that the so-called efficiency engineers who are chiefly responsible for introducing these innovations have not taken physiological advice it is not so certain that employers will be equally alive to the danger of speeding up those of their employees who are only possessed of average or even of subnormal ability It is in fact known that the first fruits of introducing such incentives to efficiency have often been the elimination of the slower workers—a fact which has hampered physiological investig tion as these are the workers who might expected first to show effects of strain Agai there is nothing inherently unfair in endeavourin to retain only the most efficient workers or rewarding work in proportion to its efficienc Such a policy however if bureaucratically applie may easily lead to strain on the average worke and we are glad to learn that the Industrial Healt Research Board are investigating conditions work where "speeding up' may be possible wit a view to discovering where the occasions f strain exist—and might be abused

To the efficiency engineer the human bod may be a machine—it is in fact a most flexib machine—but it is to the physiologist the psych logist and the general practitioner that the resul of abusing the machine come They know th units of human work cannot be ticked out li seconds on a clock they know too that variation exist not only in a group but in each individu of it Mr S WYATT one of the investigato of the Industrial Health Research Board with hi colleagues was one of the first to demonstrat variations in the hourly output of workers engage in monotonous work. Others have shown th effects of adverse environmental conditions suc as inadequate lighting heating or ventilatio If the group varies how much more does th individual vary in those personal qualities temperament and ability on which uniformit of work so greatly depends ? And how responsiv is the human worker to understanding guidance The right person in authority may better th best devised financial incentive to work. Soci health is perhaps only on the periphery of th preventive medicine target There is a dange nevertheless that conditions of work which lea to speeding up'—which dangle before eac individual a financial incentive, like a bunc of carrots before a donkey s nose—may creat so many selfish individuals as to impair the menta outlook of an industrial people who have owe their greatness at least in some measure to th pursuit of altruistic ideals

THE TONGUE OF THE DEAF

Of all sense deprivations only deafness cut off a person from his fellows because deafness—unlike blindness loss of taste and smell and lo of touch—imposes a burden not only upon th possessor but upon his *normal companions* partially deaf person compels us to speak loudly and with the stone deaf even when they are skille lip-readers we feel obliged to enunciate our word more deliberately than usual Consequently th deaf are often thrown back for companionshi upon the society of those who share their dis ability In the annual report of the Nationa Institute for the Deaf a project for *founding o* Leagues for the Hard of Hearing is discussed wit the aim of bringing deafened people into touc with each other Many of them feel their isolatio keenly and would welcome social gatherings a which no one need feel at a disadvantage The ide is to establish a league which would meet regularly at the headquarters of the institute in Gower-street, in other parts of the country local branches could be formed, the deaf meeting at first in each other's homes, and later engaging premises as their numbers increased Besides the social advantage of these gatherings they would afford opportunity for practice of lip reading which is an art of inestimable value to the hard of hearing even if they ultimately have to learn a sign language for use on occasions where they cannot conveniently face their companion.

Is it desirable to teach sign language to children as well as lip-reading—an evergreen subject of debate, recently revived in the *Times*? Among the deaf themselves there seems to be no doubt that the use of signs may prove a convenient short cut, especially for those who find particular difficulty in lip reading Nor, as more than one correspondent insists, need the gestures be other than graceful and significant The Rev ARNOLD HILL PAYNE went so far as to claim that the sign language "is far more expressive, facile, and beautiful than the English of even Shakespeare or the Authorised Version of the Old Testament" None the less, the fact remains that to the ordinary person the sight of a roomful of people gesticulating, however competently, is grotesque, and does nothing towards bridging the gulf between the deaf and those who hear Miss A B S SPRIGGE, in an article in the January issue of *Speech*, sums up the importance of lip-reading, and of speech, for those born deaf in a telling sentence "I realised that unless I did something very drastic, in order both to improve my speech and get a wider vocabulary, I should never achieve my ardent desire to have as normal a social life as possible, to enjoy friendships, and to meet artists in connexion with my work" Her account of her own education in lip-reading and speech is one of laborious and steady effort, richly rewarded It is easy to see that many of the deaf may lose heart when faced with the prolonged study which goes to make a capable lip reader with intelligible speech, and many may take refuge, perhaps too readily, in the sign language which can be so much more quickly and easily learned But for those who can, and will, make the effort the gain in normal social intercourse is so great that it may well be better to avoid teaching the sign language to the deaf until years of patient training have shown that no other speech is likely to be acquired Deaf persons of high intelligence will be quick to realise the advantages of normal speech and will make the necessary effort Those among them who have any hearing at all for the voice, if only for vowels shouted close to the ear, will in the future be able to supplement the instruction they receive from sight and touch by the use of a sound magnifier This will not lessen, indeed it may intensify, the effort required, for they will have to learn to interpret and evaluate what they hear and correlate it with what they see and feel But the results of an experiment with magnified sounds carried out by Dr PHYLLIS KERRIDGE in coöperation with Dr A G WELLS and recorded in the green book published to-day by the Medical Research Council[1] shows that an immense improvement in speech may follow the combination of aided hearing and lip reading

SYPHILIS A MAJOR PROBLEM

THE report of the Royal Commission on Venereal Diseases in 1916 and the spread of venereal infection during and after the late war aroused general interest in measures designed to combat this menace to society The public conscience was further stimulated by skilful propaganda To-day, however, the position is reversed, propaganda has in recent years been less intense, and interest is waning There is a tendency, perhaps, to be a little too complacent about the partial success of the campaign In the United States, on the other hand, a more pessimistic outlook prevails, as may be seen in two letters we have received from a correspondent in that country[2]

The first of these was based on a meeting of health officers held last April and the papers then delivered have since been published at length[3] In one of them Dr EARLE MOORE said that in the States each year no less than 1,140,000 patients with syphilis come under treatment for the first time, of whom 518,000 are suffering from early and presumably infectious manifestations while 596,000 are in the later stages of the disease From the available evidence he concluded that less than half the syphilitic patients are treated during the infectious stages—a state of affairs he attributed to public ignorance, to failures in diagnosis, and to the fact that symptoms are often absent or slight during the period of invasion MOORE believes that this annual figure of over a million new patients would be increased to three millions if all possible steps were taken to discover those who are infected he estimates that at any one time 12,000,000 persons in the United States are suffering from syphilis, of whom only 683,000 are under treatment or observation The suggestions made for grappling with this appalling problem were considered by other contributors to the symposium they fall into four main groups—namely, the finding of cases, the education of patients and public, the education of the medical profession, and the provision of better facilities for attendance by patients and for diagnosis and treatment by practitioners Case-finding is to be achieved by the zealous tracing of contacts and by introducing blood tests as a routine for all persons attending hospitals or public institutions MOORE says he showed in 1923 that before the introduction of such tests no less than 5000 patients suffering from syphilis passed annually through the in patient and out-patient departments of the Johns Hopkins Hospital without their infection being recognised For the benefit of those who believe that such a routine test is undesirable or impracticable he points to the fact that in hospital obstetric work it has achieved a remarkable reduction in the incidence of congenital syphilis Dr VONDERLEHR, writing on the education of the public health officer recommends that those who combine clinical experience in the diagnosis and treatment of venereal diseases with an intense interest in the subject should be enabled to give their whole time to the organisation and coördination of venereal disease services Dr J H STOKES however wisely maintains that ultimate success depends on the coöperation of the ordinary medical practitioner since not even the most widespread organisation will provide clinics that are accessible to all and there will always remain a proportion of patients who insist on treatment by their private doctors He believes therefore that the most important of all measures is the early instruction of the practitioner who must not only get a thorough grounding at his medical school but must have every possible chance of gaining practical experience at a clinic

[2] See *Lancet* 1936, 1, 1083 Feb 20th 1937, p 466

[3] *J Amer med Ass* Sept 5th and 12th, 1936

In his annual report for the year 1935 the chief medical officer of the Ministry of Health refers to the continued decline in the number of cases of infectious syphilis attending public clinics in this country and expresses the opinion that this is a true reflex of diminution in the incidence among the population This opinion is of course based on convincing evidence which leaves no doubt that in this respect we are much more fortunately situated than are the peoples of the United States The evidence would be even more conclusive, however if it were supported by recent figures showing the incidence of latent or undiagnosed syphilis among various sections of the population A repetition of the type of serological investigations carried out by FILDES and by COLLIE who reported to the Royal Commission of 1916 and by ASSINDER[4] in Birmingham would give useful information and supply material for a comparison with the present situation in the United States and with the situation in this country twenty years ago

MEDICAL RESEARCH

To weave the changing design of current medical research on the framework of a command paper is a task for a craftsman The administrative staff of the Medical Research Council deserve gratitude for their skilled exposition year by year of investigations completed, still in progress or only projected The actual arrangement of the report varies little from year to year the classification adopted, partly topographical and partly topical is well designed to provide a readable document and to show without wearisome overlapping the interlacing of the studies in progress at different places It so happens that much of the distinguished work outlined in the introduction to the report which is summarised on page 709 is already familiar to our readers through its original publication in THE LANCET or through editorial comment. There is much to be gained from a retrospect in proper perspective of discoveries whose significance has since been confirmed and extended It is highly encouraging to find how often hopes modestly expressed have been justified and claims made with diffidence have been substantiated No doctor, however, least of all a doctor in practice should be content with a summary of this absorbing report For three shillings he can obtain an index to the fine contributions of this generation of British workers to medical progress and its study will effectively disperse any doubts whether the parliamentary grant-in aid, this year amounting to £105 000 is being spent to good advantage

SIR AUSTEN CHAMBERLAIN

THROUGH the sudden death of SIR AUSTEN CHAMBERLAIN on Tuesday last a great figure in the political life of this country has been lost. Not long since in times of the gravest international difficulty he exercised a driving power for a grand settlement of the discords following the war which foreshadowed at its inception noble results The Locarno Treaty has not as alas all know, effected its high purposes but it represents the finest effort made for peace since the Armistice and the principles laid down at its counsels will yet have their influence though economic crises have since occurred with disastrous effect on its ideals By his work at Locarno AUSTEN CHAMBERLAIN will always be remembered We make no attempt to detail the events of his long eventful political career—he received congratulations on his maiden speech from GLADSTONE and held all the high offices under the Crown save the Premiership of which his own generosity deprived him His labours at Locarno though now frustrated, will bear fruit in the future, while his example of consistency to high ideals, of immense industry in administration and above all of personal self abnegation make of him a noble character in British politics

Always inspired by the memory of his father it was inevitable that Sir AUSTEN CHAMBERLAIN should have close at heart the status the well being and the progress of our colonial dependencies The father's achievements in the field of tropical medicine were marked with all the qualities of personal character which lift the statesman above the politician and to those qualities the son succeeded The father had seen in the devastations caused by diseases peculiar to the regions one of the chief obstacles to the development of our tropical and subtropical dependencies and the outcome was the foundation of the London School of Tropical Medicine some thirty years ago Mr NEVILLE CHAMBERLAIN as Minister of Health laid the foundation-stone of the new building in 1926 and in 1932 Sir AUSTEN accepted the position of chairman of the court of governors of what is now the London School of Hygiene and Tropical Medicine He interpreted his responsibilities in the same spirit in which he had interpreted his high charges as statesman In order that he might obtain an intimate knowledge of the activities of the school he suggested that he should become a member of the board of management and in the result attended meetings of the board with the greatest regularity, and gave close personal attention both to the business management of the school and the work of the scientific staff The incorporation of the Ross Institute with the London School of Tropical Medicine in 1934 was largely due to his influence It was typical of the pains which he took to acquaint himself with the affairs of the school that, whatever the other claims on his time might be, he attended the annual students' dinner, devoting the evening to talking with individual students The school is yet a young institution and thus suffers from the lack of endowments It was always Sir AUSTEN's hope that an adequate endowment fund for the school would be created, and meanwhile he was tireless in his efforts to secure year by year donations and subscriptions such as might enable the school not only to balance its accounts but to meet urgent demands for expansion of its activities Some years ago Sir AUSTEN gave a further example of his deep and practical interest in the progress of medicine when he became chairman of the governing body of the British Postgraduate Medical School Here again he was not content with any ornamental rôle but acquainted himself thoroughly with the affairs and personnel of the institution Medicine loses in him a tried and valuable friend

---

[4] *Bgham med. Rev* 1914 74 137

THE confusion that may arise between symptoms due to alcohol and to the after effects of insulin in connexion with motoring offences was well brought out in the mock trial organised by the Fellowship of Medicine which we report in this issue An actual case demonstrating this confusion was heard last week at Bow street police-court and is the subject of comment on p 716

ANNOTATIONS

DISEASE PREVALENCE IN U S A

EACH state of the U S.A has its own health laws, public health services and officers, and most of them issue reports of their own But the federal government exercises control over matters common to all the states and everything connected with migration from state to state, or from foreign countries So it comes about that the annual report of the Surgeon General is one of the most important of all health reports, not only to Americans, but to Europeans and, along with the report of the health commissioner with the Government of India, is looked upon as the chief annual record of epidemiological history This year the report[1] is by Dr Thomas Parran in succession to Dr H S Cumming who retired in 1936 after 42 years' service, during 16 of which he was surgeon general. From this report we derive much of our knowledge of the influence of western civilisation on diseases originating in the east, for the States are the birth place of most new infections and of modification of old ones It is, therefore, to be regretted that since the financial crisis the surgeon general's report has been cut down so much that it is difficult to follow, save by those who are familiar with the official and semi official reports of the American local health officers

To us the chief interest of the report lies in the division of scientific research and the epidemiological studies Investigation has revealed an "appalling number" of deaths from coronary occlusion, especially among white males below the age of 50 An increase of deaths in comparatively young people from forms of cardiac disease formerly ascribed to senile degeneration has also been noted in this country The observation that rats depleted of vitamin B are more susceptible to rat leprosy may have important bearing on the control of human leprosy It has long been clear that the St Louis epidemic of 1933 was not the encephalitis lethargica of Economo, further research suggests that the Los Angeles epidemic of 1934, at the time reported as poliomyelitis, was due to a fourth virus disease of the central nervous system Plague was introduced into North America at the beginning of the century and quickly became endemic in ground squirrels, the disease is spreading eastwards amongst native rodents, but human cases are not common In 1935–36 only four human cases were reported An important new fact is that the human flea carries *Pasteurella pestis* and will bite reservoir animals such as prairie dogs (marmots), as well as coyotes and deer At least four forms of typhus (rickettsia) occur in the States, of which Rocky Mountain fever is peculiar to the region from which it takes its name, this is spreading in extent and of the two forms one is highly fatal, the other benign Tularæmia is another disease first recognised in man in the Rocky Mountain region, but now known to be common in parts of Europe

The health statistics are cast for the calendar year 1935, which was a record year for good health in the States The death rate (for the 25 states furnishing data) was 10 8 and the infantile mortality 52 The maternal mortality, however, was still at the high level of 5 3 per 1000 live births New low death rates were recorded for typhoid fever and diphtheria, but poliomyelitis was severe with a total of 10,839 cases reported, against 7517 in 1934 and an average of 8249 Of recent years, poliomyelitis has been exceptionally well notified in the States, the difference between the reported incidence in America and in Britain, where notification is still faulty, is therefore partly fictitious

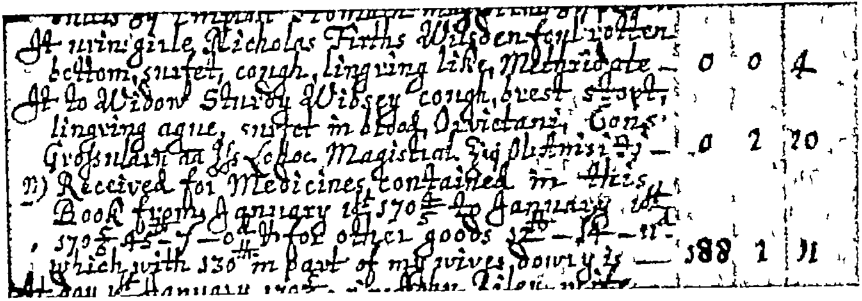
[1] Annual Report for 1936 of the Surgeon General of the Public Health Service of the United States Washington Government Printing Office 1936 Pp 155 $1

AN EIGHTEENTH CENTURY DOCTORS NOTEBOOK

"Till October 31st 1703 in old Note Book" are the words written at the top of the first page of an eighteenth century doctor's daybook, which has come into our hands through the courtesy of Mr Thomas Ottaway, coroner for St Albans The closely written pages of regular script which follow are of interest, for they give not only a detailed record of the money which the writer received day by day, but also reflect something of his way of living and working As will be seen, an entry usually consists of the name and address of the patient, a short pithy description of the symptoms, the prescription and/or treatment and then the fee Most of the entries begin with the word "Urin" which would seem to suggest that a great deal of the doctors treatment was based on uroscopy The urine is often described as having a "foul viscous bottom"



It [illegible] girle Nicholas Firths Wilden [illegible]
bottom, surfet, cough, lingring like, Methridate — 0 0 4
It to Widow [illegible] Wibsey cough, brest stopt,
lingring ague, surfet in blood, [illegible]
[illegible] Magistral [illegible] — 0 2 10
Received for Medicines contained in this
Book from January 1st 1705 to January 1st
1706 [illegible] for other goods [illegible]
which with 130 ℔ in part of my wives dowry is — 388 1 11

He does not seem to have visited his patients often at any rate he rarely records a visit. His usual fees vary from a few pence to somewhere about seven shillings The most prevalent diseases among his patients were aguish fever canker in gums windy pain in body inflamed ulcerated legs, stopt brest and a condition described as lingring like. There was a fair amount of scurvy and "rheumatismus and over and over again we find the words consumption feared A surfet of raw fruits seems to have been a common disorder among children But Robert Spence s son died of an illness which seems to have baffled and perturbed the doctor It is described as lingring convulsion, fits like possession joynts lost witchcraft feared The writer does not seem to have undertaken any obstetrics But after all though the male accoucheur had already begun to find favour in London the provinces were still prejudiced in favour of the midwife as shown by the experiences of Dr Slop several years later in the household of the enlightened Mr Shandy Sometimes our doctor says of a woman that she may be impregnate but he always seems to be actually treating her for some other condition Other fees which the doctor received are £3 4s 10*d* from a patient for advice and tabling for eight weeks and 3s 6*d* from the overseers of the poor for my horse and my own pains in going to Wakefield and Pontefract about Tim Hughes triall Another entry suggests a happy relationship between doctor and patients and a pleasant method of collecting fees— Reed of severall persons a voluntary gratuity when our friends came to visit us in all £6

At the end of each year the doctor sums up his financial position and in the first of the Decembers in his new notebook he writes received for medicines contained in the former Note Book and in this from January 1st 1702–3 to January 1st 1703–4 £50 18s 2*d* and for other goods £17 14s 8*d* being in all the sum of £70 12s 0*d* He seems to have married some time in 1705 a woman of some property for in his grand total at the end of that year is included a new item £130 in part of my wive s dowry and soon after there begin to appear receipts for rents " Reed. of Abraham Miller Skircoatt Green his Rent due to my Wife at Whitsuntide last £4 5 0 The system of deducting taxes at source seems to have been in force then and some of the rent receipts are elaborate

Received of John Pickles in Allerton his Rent due at Martinmass last deducting for poor assess, 8/– Land tax for half year 10/11¼ Constable lay 2/2¼ Mr Hayles Rent 12/2¼ window monies 3/– Church bag 2/6 at Court 2*d* Mrs Midgley rent 1/4 for stable setting 2 days 1/– gave him 11¼*d* in all £2 3 0¼ with R R and J D rents £4 10 from £11 2 there remains £4 8 11¼

Not all the entries are strictly medical: as when the calf of the starned cow is sold for five shillings or Henry Farrer of Lower Mill is let a cow s milk for one year for 10s When an animal is slaughtered Joseph Lister bought 'a fourth part of a fat cow besides the hide and tallow for 15/ while John Garnet had some of the worse tallow Many other homely details suggest a varied and pleasant life among congenial surroundings

THE DISEASES OF WILD ANIMALS

THE study of disease among wild animals has until recent years been confined chiefly to those important human or domestic animal infections such as plague tularæmia sleeping sickness nagana typhus and leptospiral jaundice, that are carried by various wild mammals The disease of the small mammals chiefly rodents used for laboratory work has more recently attracted attention Experimental epidemiology with white mouse populations has already thrown light on the processes by which epidemics come about—still one of the major mysteries of medicine The subject is finding a new extension by the discoveries of animal ecologists who find that disease is a widespread natural phenomenon in nature and especially among wild mammals, which suffer from rather violent fluctuations in population associated with periodic mortality on a large scale The annual report[1] for 1935–36 of the Bureau of Animal Population at Oxford University summarises some of the methods by which wild animal populations are being studied The approach is along three lines which cover the whole field of population dynamics The chief animals studied by this bureau are the vole or field mouse the partridge and the American snowshoe rabbit all three being species with strongly marked cycles of abundance and scarcity periodic outbreaks of disease and at the same time general economic importance Problems of census have necessitated the invention of entirely new methods for estimating density while the powers of increase are calculated from information obtained about reproductive powers length of life and breeding seasons The third phase of study mortality falls into the domain of pathology; with some ecological work on the question of predator control. Of special interest is the intensive study being made of fluctuations which occur every three or four years among wild voles (*Microtus agrestis*) on the Welsh and Scottish hills, for which purpose consignments of live voles are trapped and shipped to Oxford, where Dr A Q Wells, the Bureau's pathologist, working under Medical Research Council auspices, is undertaking a study of their diseases. One of the special features of these wild animal fluctuations is that they can be precisely followed in the field, and since the onset of periodic mortality is associated usually with high densities at the peak of each cycle, there are opportunities for finding some of the conditions in the early stages of an epidemic—a thing which is very difficult to do in human epidemics. The experimental side of the work has become possible through the domestication of the vole, as an easily maintained laboratory animal. This stage of the work has taken several years. The vole, having a rather different biological character from that of other small rodents commonly used in the laboratory, has an additional value for general pathological work. The Bureau is contemplating the study of other species in the future, and the report mentions the possible importance of extending the present number of laboratory animals by the conversion of wild rodents and insectivores for this purpose—a special job requiring an intimate knowledge of the habits and ecology of each species.

---

[1] Annual Report of the Bureau of Animal Population (University Museum Oxford) 1935–36 Pp 1–48

Such population research has to be maintained for long periods if it is to yield successful results. In this respect one is reminded of meteorology and its need for comparable observations at different stations over many years. It is therefore satisfactory that Oxford University, in conjunction with other bodies, has made arrangements to guarantee the central costs of the Bureau's work for a period of five years at any rate. In addition to the research side of the Bureau's activities, mention should be made of its work in assembling the literature on wild animal populations. A useful list of recent literature is appended, and it is stated that this can be obtained by research workers independently from the main report. A feature of this list which strikes the eye is the world-wide distribution of field and laboratory work on wild animal populations and their diseases. The Bureau, which has a staff of six workers under the direction of Mr Charles Elton, should perform a useful function in canalising information, and in promoting by its research and its library the understanding of general principles of the fluctuations of hosts and parasites, a subject of which human epidemiology forms an important part.

LYMPHOGRANULOMA INGUINALE

At the meeting in May, 1934, of the permanent committee of the Office International d'Hygiène Publique in Paris, Carl Kling, representing Sweden, suggested that lymphogranuloma inguinale should be classed with the three main venereal diseases in so far as the benefits of the Brussels Convention of 1924 were concerned. It will be remembered that this convention provided for the free treatment in certain ports of seamen suffering from syphilis, gonorrhœa, and soft sore. Kling's suggestion led to an inquiry into the frequency and behaviour of lymphogranuloma inguinale, and in May, 1935, the outcome of this inquiry was discussed in Paris. While for various reasons the disease was not on this occasion promoted to the benefits of the Brussels Convention, further research was recommended. One of the first fruits of the recommendation was a report made to the Office by Dr B Bäfverstedt of Stockholm, and some of his findings are published in *Nordisk medicinsk Tidskrift* for Feb 20th of this year. It appears that the Swedish health authorities issued circulars in 1934 and 1935 informing the medical profession that lymphogranuloma inguinale would be included among the notifiable diseases till the end of 1937. Though this administrative measure may not have become general knowledge, and though the disease in question is apt to be overlooked and taken for some ailment other than lymphogranuloma inguinale, as many as 236 cases have been diagnosed in Sweden in the decade 1927–36. The bubonic form of the disease was observed in 219 men and in 6 women, while genito-ano-rectal elephantiasis was observed in only 3 men and in 8 women. Since the inclusion of lymphogranuloma among the notifiable diseases, the annual number of notifications has been about 20 to 25. The experience of two important Swedish hospitals is that for every two cases of soft sore there is one of lymphogranuloma requiring hospital treatment. This takes about eight weeks on the average and consists of incision or extirpation of the lymphatic glands, the intravenous injection of metallic salts, and vaccination with Frei's antigen. Radiological treatment has been attempted in some cases as well as treatment with artificial malaria. With regard to operative treatment, Bäfverstedt considers that the fear of post-operative elephantiasis is much exaggerated, and he knows of no such case in Sweden.

SECOND ATTACKS OF INFECTIVE DISEASE

It has long been a subject of speculation why certain infective diseases confer a more or less lasting immunity while others appear to give no immunity at all, indeed, in some cases, appear to dispose to further attacks. To a limited extent we have found explanations for these vagaries in immunity. In diphtheria, for example, we know that the insusceptibility conferred by an attack is associated with the development and persistence of antitoxin in the blood and that if the antitoxin falls below a certain level the chance that susceptibility will return becomes proportionately greater. The same explanation holds for scarlet fever, but here there are elements in addition to those that can be ascribed to a toxin, if scarlet fever in its complete clinical form rarely attacks the same person twice, there is reason to suppose that he may still suffer from further attacks of disease due to essentially the same microbic cause. There are diseases such as erysipelas, pneumonia, and the common cold where, at times at least, it appears that one attack only makes a later attack more likely. There are others such as typhoid, measles, and yellow fever where one attack almost always confers a lasting immunity. There are, again, diseases such as tuberculosis where an immunity can be experimentally demonstrated which is difficult to assess under the conditions of ordinary life. In spite of its many triumphs humoral immunity has failed to give us any final explanation as to the essential conditions of insusceptibility for most infective diseases. The decisive factor may be, and probably often is, a function of the cells or tissues, but we know very little as to the differences in behaviour between normal and immune cells and that little has shed less than the expected light on the actual problems of medicine. In a paper recently read before the Ipswich Medical Society, Dr Herbert H Brown discussed the possibility that those infections associated with a mononuclear (reticulo-endothelial) response are followed by a lasting immunity, while those associated with a polymorphonuclear response are followed by little or no immunity In support he quotes typhoid fever cholera, variola and vaccinia as examples of diseases with a mononuclear response pyogenic infections herpes simplex and the common cold as examples of those with a polymorphonuclear response That the facts of disease are in general agreement with Dr Brown s thesis cannot be denied and must have occurred to many observers of infections but there are difficulties in accepting the explanation in toto The toxigenic diseases such as diphtheria or tetanus are included by Dr Brown in the reticulo endothelial response group and he accepts the view supported to some extent by recent experimental work that this system is the main place for the elaboration of antibodies The exact part taken by the reticulo-endothelial system in the formation of antibodies is however still too uncertain to bear the weight of any secondary hypothesis Tuberculosis syphilis and the protozoal diseases do not readily fit into the scheme. We question whether the common cold can be correctly termed a disease with a polymorphonuclear response. In the present state of knowledge it would be unsafe to build too much on this apparent correlation between immunity and cellular response Some day we may find a rational explanation for it.

LONDON WATER ON VIEW

Increasing attention is being given to the effect of the micro flora and fauna of water other than bacteria on the use of water for domestic and other supplies Although many workers including Leeuwenhoek Ehrenberg and Savile Kent, have described and classified the diatoms and other algæ the infusoria and the animalcules which live in water their ecology has especially perhaps in this country received little attention. It is now being realised how much they prejudice the water-supply: whether by their growth in supply pipes which increases surface friction and decreases delivery capacity or by producing those tastes and odours which, apart from actual harm irritate and disgust consumers Some years ago the British Museum (Natural History) staged in the central hall at South Kensington an exhibit, arranged by R Kirkpatrick, in which amongst other things were shown the fresh water mussels which in the larval stage had passed through filter beds to reach maturity in the pipes A more comprehensive exhibit has now been set up in collaboration with the Metropolitan Water Board. The pipe fauna includes sponges and polyzoa (which as they grow harbour other creatures) molluscs hydroids eels and leeches The uncovered cistern forms a miniature lake in which the resting forms of organisms floating in the air may settle and grow Although rivers are nearly free from small organisms, the reservoirs in which river water is stored form good growing grounds for them and in fact develop typical lacustrine populations Iron bacteria have at times given cause for anxiety The growth in reservoirs of organisms which live but do not flourish well in rivers is illustrated by a series of photomicrographs taken at fortnightly intervals of the plankton of a reservoir showing the development of stephanodiscus a diatom which increased from Dec. 29th when very few were present to a maximum on Feb 9th when the numbers were enormous whilst by March 22nd the numbers had fallen to the same order as in December The control of algæ by coagulants and by algicides is illustrated and a series of graphs shows the successive diminution in numbers of coliform bacilli in raw river water stored water water after primary filtration secondary filtration and treatment with chloramine The minima in all cases occurred in July The exhibit is very lucidly set out and may be commended to lecturers on public health subjects as likely to give their pupils as much instruction in half an hour as could be assimilated in several formal lectures

THE PREVENTION OF POST ANÆSTHETIC LIVER DAMAGE

The evil effect of some anæsthetics upon the parenchyma of the liver has long been known and delayed poisoning from chloroform is regarded as the classic example. Experimentally ether by very prolonged administration and Avertin have also been shown to produce necrotic changes in the liver cells. It has never been suggested however on clinical grounds that there is any association of these injurious effects with oxygen shortage and the only preventive and remedial measures have been confined to giving a high carbohydrate diet beforehand and glucose by mouth rectum or vein after operation Recent experimental work by Goldschmidt Ravdin and Lucké[1] shows that at any rate in the dog mixing certain anæsthetics with pure oxygen instead of air has a great influence in preventing damage that would otherwise occur the oxygen having a definite protective action They administered chloroform to dogs for an hour some having air and the others oxygen and killed them four days later, when they found considerable differences between the two groups The livers of those dogs that had inhaled oxygen were abnormal in only 32 per cent, while with air there was necrosis in 73 per cent this being extreme in 10 per cent. Similar results were obtained with divinyl ether They went on to investigate the question whether anoxæmia of itself without any anæsthetic, could be responsible for similar effects and they proved that it could Dogs submitted to an atmosphere of 15 per cent oxygen and 85 per cent nitrogen for two hours, and subsequently examined post mortem showed degenerative liver changes in 28 per cent These experiments seem to be important in giving scientific support to the already common practice of adding pure oxygen to inhaled anæsthetics If what is true of the dog holds good in man this oxygen inhalation will be as effective in preventing liver damage as the usual several days preoperative administration of a high carbohydrate diet

ASSOCIATION OF INDUSTRIAL MEDICAL OFFICERS.—At a quarterly meeting of this association held in the London School of Hygiene, Keppel-street on March 12th Dr L. P Lockhart being in the chair a discussion on Accident Proneness was opened by Mr Eric Farmer reader in industrial psychology Cambridge University He briefly summarised the investigations which he and other workers had carried out on accident proneness and put forward certain suggestions for future coöperative work between the Industrial Health Research Board and industry if practicable through the industrial medical officer.—Dr F H C Beards (I C.I Billingham) read a paper on the Organised Treatment and Rehabilitation of the Injured Workman He outlined the progress of the patient from the time of injury to the time of resuming work and the difficulties of the present procedure in rehabilitation making suggestions for improvement He divided accidents into minor and major cases remarking that in importance they were equal He would like to see the provision of alternative work schemes in industry; this could best be done he thought by coöperative effort of industrial medical officer and works management Only the larger firms could afford to employ whole- or part time medical officers but he felt that much more could be done to help the smaller concerns.

PRINCIPLES OF MEDICAL STATISTICS

XII—COMMON FALLACIES AND DIFFICULTIES

In the following sections I have set out examples of the misuse of statistics In some of them the actual figures have been taken from published papers, in others hypothetical figures have been used to indicate the type of error which has led the worker to fallacious conclusions No principles are involved that have not been discussed in the previous sections The object is merely to illustrate, at the risk of "damnable reiteration," the importance of these principles by means of simple numerical examples (in some instances—e g, (*a*) below—the figures are deliberately exaggerated to make clearer the point at issue) The fact that in practice such grossly exaggerated differences rarely occur does not lessen the importance of accurate statistical treatment of data Differences do occur very often of a magnitude to lead to erroneous conclusions, if the data are incompetently handled in the ways set out

Mixing of Non-comparable Records

(*a*) Let us suppose that in a particular disease the fatality rate is twice as high amongst females as it is amongst males, and that amongst male patients it is 20 per cent and amongst female patients 40 per cent A new form of treatment is adopted and applied to 80 males and 40 females, 30 males and 60 females are observed as controls The number of deaths observed amongst the 120 *individuals* given the new treatment is 32, giving a fatality rate of 26 7 per cent, while the number of deaths observed amongst the 90 *individuals* taken as controls is 30, giving a fatality rate of 33 3 per cent Superficially this comparison suggests that the new treatment is of some value, in fact that conclusion is wholly unjustified, for we are not comparing like with like The fatality rates of the total number of individuals must be influenced by the proportions of the two sexes present in each sample, males and females, in fact, are not equally represented in the sample treated and in the sample taken as control Tabulating the figures shows the fallacy clearly (Table XIV)

TABLE XIV

—	Males	Females	Males and females combined
Normal fatality rate	20 %	40 %	—
Number of patients given new treatment	80	40	120
Deaths observed in treated group	16	16	32
Fatality rates observed in treated group	20 %	40 %	26 7 %
Number of patients used as controls	30	60	90
Deaths observed in control group	6	24	30
Fatality rates observed in control group	20 %	40 %	33 %

The comparison of like with like—i e, males with males and females with females—shows that the treatment was of no value since the fatality rates of the treated and untreated sex groups are identical, and equal to the normal rates Comparison of the total samples, regardless of sex, is inadmissible for the fatality rate recorded is then in part dependent upon the proportion of the two sexes that are present There are proportionately more females amongst the controls than in the treated group and since females normally have a higher fatality rate than males their presence in the control group in relatively greater numbers must lead to a comparatively high fatality rate in the total sample Equally their relative deficiency in the treated group leads to a comparatively low fatality rate in that total sample No comparison is valid which does not allow for the sex differentiation of the fatality rates

An actual example of this error is in the record of a less favourable reaction of females to forms of treatment for syphilis It should not be forgotten that when two such forms of treatment are being compared, sex differentiation, in assessing the results (or sex equality in the two groups), may be of *importance*

(*b*) One more example of the result of mixing non comparable records may be given The following (hypothetical) figures show the attack rates of a disease upon an inoculated and an uninoculated population (Table XV)

TABLE XV

Year	Number of persons		Number of persons attacked		Attack rates per cent	
	Inoc	Uninoc	Inoc	Uninoc	Inoc	Uninoc
1935	100	1000	10	100	10	10
1936	500	600	5	6	1	1
1935 and 1936	600	1600	15	106	2 5	6·6

In each calendar year the attack rate of the inoculated is equal to the attack rate of the uninoculated. Between 1935 and 1936 there has, however, been a large change in the size of the inoculated and uninoculated population and also a large change in the level of the attack rate Summation of the results for the two years leads to the fallacious conclusion that the inoculation afforded some protection The large uninoculated population in 1935 when the attack rate was high leads to an absolutely large number of cases—though in relation to their numbers the uninoculated are at no disadvantage compared with the inoculated The inoculated cannot contribute an equal number of cases for the population at risk in that year (1935) is far smaller Thus amalgamation of the unequal numbers of persons exposed to

TABLE XVI

Year	Number of persons		Number of persons attacked		Attack rates per cent	
	Inoc	Uninoc	Inoc	Uninoc	Inoc.	Uninoc
1935	100	1000	10	100	10	10
1936	500	600	50	60	10	10
1935 and 1936	600	1600	60	160	10	10
1935	500	600	50	60	10	10
1936	500	600	5	6	1	1
1935 and 1936	1000	1200	55	66	5 5	5 5

different risks in the two years is unjustified No fallacy would have resulted if the attack rate had not changed or if the proportions exposed to risk had not changed as the above figures show (Table XVI)

When the populations at risk and the attack rates *both* vary the calendar year becomes a relevant factor and must be taken into account by the calculation of rates within the year

Such a problem does arise quite frequently in practice for example in assessing the incidence of diphtheria on immunised and unimmunised children The numbers in the immunised group vary from year to year and the incidence of diphtheria also varies Summation of the experience over a series of years may lead to an erroneous conclusion of the type illustrated

Neglect of the Period of Exposure to Risk

(*a*) A further fallacy in the comparison of the experiences of inoculated and uninoculated persons lies in neglect of the time during which the individuals are exposed first in one group and then in the other Suppose that in the area considered there were on Jan 1st, 1936 300 inoculated persons and 1000 uninoculated persons The number of attacks are observed within these two groups over the calendar year and the annual attack rates are compared This is a valid comparison *so long as the two groups were subject during the calendar year to no additions or withdrawals* But if as often occurs in practice persons are being inoculated *during* the year of observation the comparison becomes invalid unless the point of time at which they enter the inoculated group is taken into account

Suppose on Jan 1st 1936 there are 5000 persons under observation none of whom are inoculated that 300 are inoculated on April 1st a further 600 on July 1st and another 100 on Oct 1st At the end of the year there are therefore, 1000 inoculated persons and 4000 still uninoculated During the year there were registered 110 attacks amongst the inoculated persons and 890 amongst the uninoculated If the ratio of recorded attacks to the population *at the end of the year* is taken then we have rates of 110/1000=11·0 per cent amongst the inoculated and 890/4000=22 3 per cent amongst the uninoculated a result apparently very favourable to inoculation This result however *must* be reached even if inoculation is completely valueless for no account has been taken of the unequal lengths of time over which the two groups were exposed None of the 1000 persons in the inoculated group were exposed to risk for the *whole* of the year but only for some fraction of it for a proportion of the year they belong to the uninoculated group and must be counted in that group for an appropriate length of time

The calculation should be as follows:

All 5000 persons were uninoculated during the first quarter of the year and therefore contribute (5000 × ¼) years of exposure to that group During the second quarter 4700 persons belonged to this group—i.e 5000 less the 300 who were inoculated on April 1st—and they contribute (4700 × ¼) years of exposure to the uninoculated group During the third quarter 4100 persons belonged to this group—i e 4700 less the 600 who were inoculated on July 1st—and they contribute (4100 × ¼) years of exposure Finally in the last quarter of the year there were 4000 uninoculated persons—i e 4100 less the 100 inoculated on Oct 1st—and they contribute (4000 × ¼) years of exposure The person years of exposure in the uninoculated group were therefore (5000 × ¼) + (4700 × ¼) + (4100 × ¼) + (4000 × ¼) = 4450 and the attack rate was 890/4450 =20 per cent —i e., the equivalent of 20 attacks per 100 persons per annum Similarly the person years of exposure in the inoculated group are (0 × ¼) + (300 × ¼) + (900 × ¼) + (1000 × ¼) = 550 for there were no persons in this group during the first three months of the year 300 persons during the second quarter of the year 900 during the third quarter and 1000 during the last quarter The attack rate was, therefore 110/550 = 20 per cent and the inoculated and uninoculated have identical attack-rates Neglect of the durations of exposure to risk must lead to fallacious results and must favour the inoculated The figures are given in tabulated form (Table XVII)

TABLE XVII

Inoculated at each point of time	Inoculated		Uninoculated	
	Exposed to risk in each quarter of the year	Attacks at 5 per cent. per quarter	Exposed to risk in each quarter of the year	Attacks at 5 per cent per quarter
Jan 1st, 0	0	0	5000	250
Apr 1st, 300	300	15	4700	235
July 1st, 600	900	45	4100	205
Oct 1st 100	1000	50	4000	200
Total at end of the year	1000	110	4000	890

Fallacious comparison—Ratio of attacks to final population of group Inoculated 110/1000=11·0 per cent Uninoculated 890/4000=22 3 per cent

True comparison.—Ratio of attacks to person years of exposure Inoculated 110/(300 × ¼) + (900 × ¼) + (1000 × ¼) =20 per cent Uninoculated 890/(5000 × ¼) + (4700 × ¼) + (4100 × ¼) + (4000 × ¼) = 20 per cent

This example is an exaggerated form of what may (and does) happen in practice if the time factor is ignored Clearly even if the time-factor is allowed for interpretation of the results must be made with care If the inoculated show an advantage over the uninoculated it must be considered whether at the point of time they entered that group the incidence of the disease was already declining due merely to the epidemic swing But that is another point

(*b*) A cruder neglect of the time factor sometimes appears in print and may be illustrated as follows In 1930 a new form of treatment is introduced and applied to patients seen between 1930 and 1935 The proportion of patients still alive at the end of 1935 is calculated This figure is compared with the proportion of patients still alive at the end of 1935 who were treated in 1925–29 prior to the introduction of the new treatment Such a comparison is of course inadmissible The patients seen in 1925–29 have by the end of 1935 had 6 to 11 years in which to succumb with an average exposure of 8½ years if their attendances were equally spread over 1925–29 The patients seen in 1930–35 have had only 0 to 6 years in which to succumb with an average exposure of 3 years if there attendances were equally spread over 1930–35 To be valid the comparison must be between the survival rates at equal stages of time 1 2 3 years &c after treatment

Absence of Exposed to Risk or Standard of *Comparison*

It often happens that an investigation is confined to individuals marked by some characteristic

(*a*) For example a detailed inquiry is made into the home conditions of each infant dying in the first year *of life* in a certain area over a selected period of time and it is found that 17 per cent of these infants lived under unsatisfactory housing conditions Do such conditions or factors associated with them lead to a high rate of infant mortality? The limitation of the inquiry to the dead makes it quite impossible to answer this question We need information as to the proportion of *all* infants who were born in that area over that period of observation who live under unsatisfactory housing conditions If 15 per cent of *all* infants live under such conditions, then 15 per cent of the deaths may reasonably be expected from those houses and unsatisfactory housing appears unimportant If on the other hand only 5 per cent of *all* infants are found in these conditions but 15 per cent of the deaths come from such houses, there is evidence of an excess of mortality under the adverse conditions In practice it may be impossible for financial or administrative reasons to investigate the home conditions of all infants It should be possible, however, to inquire into a random sample of them, say every tenth birth registered in the area over a given period of time Without some such standard of comparison no clear answer can be reached. Such limited investigations have been made into the problems of both infant and maternal mortality

(*b*) After very careful inquiry it is shown that of motor car drivers involved in accidents a certain proportion, say three quarters, had consumed alcohol during some period of hours previous to the accidents, and one quarter had not The deduction that alcohol contributes to the risk of accident is not justified from these figures alone It is well recognised that white sheep eat more than black sheep —because there are more of them Before the ratio of 3 " alcoholics " to 1 " non alcoholic " amongst the accident cases can be interpreted, information is also required as to the comparable ratio amongst drivers *not involved in accidents* Suppose, for example, there are 1000 drivers on the roads, and 48 accidents are recorded. Of the 48 drivers involved in these accidents three-quarters are found to have consumed alcohol—i e , 36—and one quarter—i.e , 12—have not If three quarters of *all* the 1000 drivers have consumed alcohol within a few hours of driving and one quarter have not, then the populations " exposed to risk " of accident are 750 and 250 The accident rates are, then, identical—namely, 36 in 750 and 12 in 250, or 4 8 per cent in each group A knowledge of the exposed to risk, or of the ratio of alcohol consumers to non consumers in a random sample of all drivers, is essential before conclusions can be drawn from the ratio in the accident cases

Careful inquiry into the destination of drivers involved in accidents on a Sunday morning might show that a larger proportion was driving to golf than to church. The inference that driving to golf is a more hazardous occupation is not valid until we are satisfied that there are not, in this case, more black sheep than white sheep [1]

Association, Direct or Indirect

It has been observed that while the death rate from cancer has been rising the sale of bananas in England and Wales has also been increasing No one (so far as I know) has deduced from this relationship in time a relationship of cause and effect But such a deduction would be no less logical than many that are drawn from time relationships—e g , the relationship of the cancer death rate to a hundred and one aspects of " modern " life

More often the time relationship is used as further evidence of a cause and effect expected on the grounds of quite other evidence—e g , experimental results

(*a*) For instance, the effect of bacteriophage is measured by comparing the incidence of cholera in two areas, one in which bacteriophage was distributed, the other serving as a standard of comparison In the former the incidence is found over an observed period of time to be at a lower level than the incidence in previous years or in the area observed as a control (the question of duration of exposure to risk, dealt with above, having been properly observed). It is clear that there is an association both in time and space between the incidence of cholera and the administration of bacteriophage Is that association one of cause and effect ? The answer must be that the results are perfectly *consistent* with that hypothesis, but that consistency is not the equivalent of proof. The incidence of epidemic disease fluctuates both in time and space for unknown reasons, and the abnormally low attack rates in the area in which bacteriophage was administered *may* be the result of the influence of those undetermined natural causes operating at the same time as the experiment was carried out Repetition of the experiment in another area with equivalent results would strengthen the hypothesis that bacteriophage was beneficial. With observations of this kind, limited in time and space, it is well to reflect upon the fact that " if when the tide is falling you take out water with a twopenny pail, you and the moon together can do a great deal " The history of scarlet fever may well be remembered, in this connexion, as illustrated by the testimony of R J Graves (" A System of Clinical Medicine," Dublin, 1843) In the first few years of the nineteenth century the disease " committed great ravages in Dublin " and was " extremely fatal." After the year 1804 it assumed a " very benign type " and was " seldom attended with danger until the year 1831 " In 1834 it again took the form of a " destructive epidemic " The low fatality after 1804 was " every day quoted as exhibiting one of the most triumphant examples of the efficacy " of new methods of treatment But Graves candidly admits that " the experience derived from the present [1834–35] epidemic has completely refuted this reasoning, and has proved that, in spite of our boasted improvements, we have not been more successful in 1834–5 than were our predecessors in 1801–2 " (quoted from Charles Creighton's " History of Epidemics in Britain," Camb Univ Press, 1894, Vol II, pp 722–25)

(*b*) During an epidemic individuals are, *at their own request*, inoculated, and are found to suffer a lower attack rate than that of the uninoculated. This result is clearly consistent with the hypothesis that the inoculation was beneficial. On the other hand, the association may be an indirect one Presuming that the inoculated and uninoculated groups were equal in such characteristics as age, sex, and duration of exposure to risk, it is possible that they were differentiated in other relevant ways Those who voluntarily come forward for inoculation may consist of individuals who also take other precautionary measures to avoid infection—e g , the avoidance of theatres and cinemas during the epidemic period They may belong to a class higher in the social scale and be less exposed to the risk of infection thereby—e g , by living in less crowded conditions or by being better nourished. In comparing the inoculated with the uninoculated we must always consider closely whether we are in fact comparing like with like—except in the one respect of inoculation

[1] Lest it should be thought that undue stress is being laid upon the obvious the following quotation from a debate in the House of Lords may be of interest A noble Lord is reported (*Times* Feb 7th 1936) to have said that only 4 per cent of the drivers involved in fatal accidents were women and that was because they drove *more slowly* Without evidence of the hours of driving endured (perhaps a fitting word nowadays) by each sex—and perhaps of the type of area—that conclusion cannot be justified

MEDICAL RESEARCH COUNCIL

ANNUAL REPORT 1935–36

THE report of the Medical Research Council for 1935–36[1] begins on a note of welcome to Lord Balfour of Burleigh as the new chairman succeeding Lord Linlithgow and of congratulation to Sir Henry Dale F R S director of the National Institute for Medical Research on the award of the Nobel prize for medicine jointly with Prof Otto Loewi of Graz

This award recognises their work on the nature of the chemical mechanism involved in the transmission of nerve impulses Sir Henry Dale and his co-workers showed that acetylcholine is the chemical transmitter not only of the vagal impulse to the heart muscle but of other parasympathetic nerve activities and also of some sympathetic actions They have now established that acetylcholine is also the medium through which motor nerve impulses activate voluntary muscle probably indeed the transmission of the effects of most efferent impulses throughout the peripheral nervous system is dependent at some stage or other on this chemical action

The physiological and clinical implications of this brilliant work are not yet explored Already however it has provided a scientific basis for Dr Mary Walker's discovery that prostigmin alleviates cases of myasthenia gravis and there are indications that some compounds closely allied to acetylcholine, but more stable may have therapeutic value

It is customary for the council to select for comment in an introductory survey some dozen from the various schemes of research in progress This year increased space has been allocated to this survey which deals with clinical research; influenza nutrition; the prevention and treatment of childbed fever deafness the experimental study of epidemics; cotton dust asthma; tuberculous treatment by artificial pneumothorax and medical research in the tropics

Clinical Research

Lord Nuffield's gift to Oxford is welcomed as being fully in accord with the policy of the council particularly in its establishment of senior clinical posts on a nearly whole time basis Reference is made to the handicapping effect on research in clinical medicine and surgery of the claims of private professional practice and to the tendency for promising clinical investigators either to become increasingly absorbed by their patients or to transfer their interests to research in other fields The increase in the number of substantially whole-time clinical posts candidates for which are expected to have had experience in research makes the opportunities at Oxford and on a smaller scale at Cambridge under the direction of Prof J A Ryle, of special importance The council's contribution to the training of investigators in clinical science and experimental pathology during the year under review has been the establishment of six post-graduate studentships and four research fellowships.

Influenza

The investigations on influenza at the National Institute for Medical Research by Sir Patrick Laidlaw F R S Dr C H Andrewes Dr Wilson Smith and Dr Stuart Harris (holding a Royce fellowship) have made substantial progress Attention is here drawn to three aspects of it.

(1) *World wide diffusion of the virus originally isolated and identified at the Institute*[2]—Filtered nasal washings from patients suffering from typical influenza in widely distant parts of the world (as England Porto Rico Philadelphia Alaska, Australia Holland European Russia) when inoculated into ferrets causes the appearance of the same virus in their respiratory passages this virus will then infect other ferrets and can be transmitted to mice This evidence suggests strongly that the virus thus propagated in the ferret is the primary infective agent of epidemic influenza in man.

(2) *Transmission of ferret influenza to man*—The accidental infection of one of the team of workers from a ferret and the subsequent demonstration of antibodies in his blood-serum which had previously been negative provided the important link completing the chain of evidence for the identity of the virus maintained and studied for over two years in ferrets as the cause of human influenza it also provided additional evidence of a connexion between the virus-neutralising antibody in the blood-serum and resistance to infection Negative evidence pointing in the same direction has been obtained by Dr Stuart Harris who found that blood-sera of inhabitants of St Helena, which escaped the pandemic of influenza in 1918 had no neutralising antibody for the virus These islanders have since suffered from an epidemic disease resembling influenza and samples of sera from persons affected are being examined

(3) *Possibility of immunising man against influenza*—Substantial progress has been made by Dr Andrewes and Dr Smith towards the production from the virus of a vaccine potent and pure enough to be worth testing for its value in immunising the human subject A virus of such potency has been obtained that the filtrate from the lungs of infected mice is able to infect a mouse in a dilution of one in ten million; and this virus can be made completely non infective without appreciable loss of antigenic value by treatment with very weak formaldehyde The virus in the living state is apparently innocuous when given by hypodermic injection and is being used in that way for immunisation trials in the United States

A vaccine purified by ultrafiltration has been found in the mouse to confer a substantial degree of resistance to infection by the respiratory passages, and trials of its immunising effect on man are in progress

It would be premature to attempt to estimate the probability of practical success with such methods Though a virus extracted from the infected mouse lung or from a culture on chicken embryo will newly evoke the specific neutralising antibody in the blood of a human subject or produce an increase of this antibody if it is already present it remains uncertain whether the amount of circulating antibody thus produced will confer a significant degree of resistance to naturally acquired infection or if it does how long such resistance would last But there is ample justification for hope

Nutrition

The relative importance of nutrition and exercise in the promotion of bodily and mental fitness is discussed; physical development and health are primarily dependent on proper feeding and exercises whether as games or drill are subsidiary to this and their full benefits can be obtained only in those whose bodily and mental qualities have been developed to their innate maximum by proper feeding

Among the investigations of nutritional factors supported by the council those deemed worthy of special remark are the studies by Prof E P Cathcart and Mrs A T M Murray of the ordinary diet of families in various towns, notably in St Andrews, Cardiff, Reading, and Glasgow Though the types of foodstuffs eaten varied within wide limits the distribution of calories between protein, fat, and carbohydrate eaten by people in different towns was found to be remarkably constant

---

[1] Report of the Medical Research Council for the year 1935–36 London H M Stationery Office 193 Pp 172 3s

[2] *Lancet*, 1933 2 60.

According to these workers the daily diet of 109 women students (average age 21), whose general physique and health was reported to be very good, contained 2035 calories per person

Doubt is expressed whether much misplaced trust is not being put on the 3000 calorie intake as a standard figure The council point out that the Technical Commission on Nutrition, appointed by the Health Section of the League of Nations, decided that a daily allowance of 2400 calories net is adequate to meet the energy requirements of an adult, male or female, living an ordinary everyday life in a temperate climate and not engaged in manual work

Steps designed to improve the physical fitness of the community must take account of both the educational and economic aspects of this problem Even if there were abundant money for food expenditure in every household, ignorance and stupidity would often prevent the maximum nutritional benefits from being obtained, but the limiting factor in a large section of the community remains the food purchasing power

Dr R A McCance has analysed, for some fifteen different constituents, the chemical composition of some British foods, and the losses which they undergo during cooking 87 kinds of fish, 45 cuts of meat, 12 different birds, 65 fruits and 67 vegetables were studied, without ignoring the limitations of direct chemical analysis of food as a guide to its nutritional value Many accepted theories about cooking were not supported by the experimental evidence—e g, it makes no difference to the losses whether meat is plunged into boiling water at the start or placed in cold water and slowly brought to the boil, and although vegetables lose nutrients rapidly when they are cooked in water, they may be soaked and washed in cold water in the raw state without loss

Since diets can seldom be weighed or measured until after they have been prepared and cooked, the value of having reliable figures for the chemical composition of cooked foods should be appreciated not only by physicians but by those in charge of the dietetic departments of hospitals

Influence of Diet on Decay of Children's Teeth

The council observes that the theory advanced by Mrs M Mellanby on dental decay—that a dominant factor in determining the structure of the teeth and their resistance to decay is the nutritional condition of the body, and more particularly the supply of specific food elements provided to the teeth in early life—is based on experimental and clinical evidence which has been generally accepted by scientific workers, but it has met with criticism and even denial from some dentists It is almost impossible in a field experiment with children to secure controlled conditions in which all factors can be stabilised except the one under test, especially when this is a biological agent applied over a long period However, the results of a trial over a restricted period and subject to inevitable limitations which was undertaken at Birmingham on children living in institutions support convincingly the previous findings of Mrs Mellanby They are in agreement with her view, so far as vitamin D is concerned, that the teeth—like other organs of the body—are strongly influenced by nutritional factors brought to bear upon them, either through their blood supply or indirectly through the saliva The dental decay that developed in the children receiving vitamin D was definitely less than in the control children not receiving the additional amount of this substance

In one other important respect confirmation of earlier work by this report is deemed worthy of mention The less obvious forms of imperfect dental structure (hypoplasia), described by Mrs Mellanby in 1923 as not only widespread among children in this country but also directly related to liability to decay, were seen to be present in a large proportion of these children, whereas gross defects of structure (the "hypoplasia" of the text-books) were comparatively rare A direct relationship between the structure of the teeth and decay was also found.

These sample tests of Mrs Mellanby's thesis support the view that the most promising method, according to present knowledge, of improving the dental condition of this country is to increase consumption of milk and other dairy and market-gardening produce which benefit dental structure and resistance, and especially in the earlier years of life to reduce the consumption of bread and other cereals which either actively or passively result in the developmnt of defective teeth By this means it may be expected at least that the teeth of the next generation will be greatly improved.

Prevention and Treatment of Childbed Fever

After Dr Dora Colebrook's demonstration that hæmolytic streptococci, the micro organisms responsible for puerperal sepsis, are not present in the birth canal of normal women, but are conveyed thereto from the respiratory tract or skin of medical attendants, or of friends, or of the patients themselves, came the cheering news of the remarkable success apparently achieved at Queen Charlotte's Hospital by Dr Leonard Colebrook and his colleagues in combating this infection even when it is well established They used the German dye Red Prontosil and Prontosil Soluble, and are now making clinical tests of the colourless substance para aminobenzene sulphonamide, which is allied in composition to red prontosil, since experiments in progress suggest that it gives even better results[3] During the years 1931 to 1935, 495 cases of puerperal sepsis entered Queen Charlotte's Hospital, and of these 112 died, giving a fatality of 22 7 per cent In part of the year 1936, 64 cases of puerperal sepsis were treated by red prontosil and prontosil soluble in the same hospital, of these cases only 3 have died, giving a fatality of 4 7 per cent Moreover, there has been a sudden reduction in the severity of peritonitis associated with puerperal sepsis in cases treated with prontosil, and none of these patients developed a palpable pelvic or abdomino pelvic inflammatory mass or abscess after the beginning of treatment, although this is ordinarily one of the commonest complications of puerperal infections by hæmolytic streptococci If caution is still necessary in claiming success for this treatment it is because of the signs of a general diminution in the severity of puerperal sepsis in this country during the past five years, but a change in fatality rate from 22 7 to 4 7 per cent is at least strongly suggestive of the value of these new drugs, quite apart from the published records of surprising recoveries in individual cases Reliance on curative drugs must in any case be the third line of defence in the fight against puerperal sepsis The first line must be the conduct of childbirth in such a way as to prevent (*a*) access of pathogenic organisms, especially streptococci associated with sore throat to the birth canal of women, and (*b*) transport of these organisms from the skin and other parts of the body Secondly the resistance of pregnant women should be raised to the highest possible level by an ample supply of milk, green vegetable and other protective foods

[3] See *Lancet* 1936 2 1310 and 1323

Deafness

The aspects of deafness which have been studied are (1) the actual range of defect in hearing as regards frequency and amplitude of sound in individual people and the amount of improvement that can be produced by mechanical means on the basis of this detailed knowledge (2) the degree to which deafness gives the clue to apparent mental retardation (3) prevention of acquired deafness

Dr and Mrs A. W G Ewing and Dr T S Littler have found that the results obtained by testing patients for a series of pure tones by means of the audiometer provide a reliable index of the intelligibility of speech to the deaf listener and in teaching that the class amplifier has a number of definite advantages over individual aids

Dr Phyllis Kerridge has concluded from the results of careful study that nearly all partially deaf children would benefit greatly by hearing-aids whereas among the deaf children—i.e those who cannot hear the conversational voice as far as two feet away—more than half would derive considerable benefit from sound magnification instruments

As to prevention the reports by Dr T E Banks and Dr Parkes of a lower incidence of inflammation of the middle ear and other sequelæ of scarlet fever and measles following the use of sera in London County Council hospitals are noted with satisfaction and the extension of such forms of treatment in these and other directions is anticipated

Experimental Study of Epidemics

There have been many productive clinical investigations into epidemic diseases but certain fundamental problems of epidemiology have resisted field investigation On the other hand a close experimental study of animals in a herd exposed to infection has already answered certain questions relative to human epidemics and may be expected to answer more in the future For the last 18 years a team now working at the London School of Hygiene and Tropical Medicine have exposed large numbers of mice to different infective agents and have studied their mortality rates and possible methods of altering these rates

It appears that in large herds or groups living under conditions favourable to the spread of epidemic disease and receiving regular additions of healthy animals the disease will persist indefinitely It also appears that under such conditions the form of the mortality curve and the size of the herd is determined in the main by the rate of immigration In certain epidemics the rate of mortality during the early days of herd life is very high, approximately half the entrants being dead after 2 days and three-quarters to four fifths after 50 days Between the 40th and 60th days of cage life the mortality rate reaches a low level The expectation of life from the 70th to the 90th day rises continuously but never reaches the expectation of normal mice living in the same environment but not in contact with an infective disease It is considered that these events show that both selection (by death of the more susceptible) and natural immunisation play a part in the increased average resistance displayed by surviving mice and that natural immunisation is more important than selection

As regards possible methods of interfering with the normal course of infected herds three of these have been studied—artificial immunisation changes in diet and bacteriophage The best results were obtained with artificial immunisation but a complete immunity was never obtained the dietary experiments were negative but recently Dr Marion Watson working in association with Prof W W C Topley F R S has obtained results which suggest that diet has a powerful influence on the mortality rates of mice infected artificially with *Bacillus aertrycke* Similarly the negative results obtained with bacteriophage are regarded as by no means conclusive Active immunisation though it has failed in these experiments to give results as successful as those reported from the field has significantly increased the expectation of life particularly in ectromelia epidemics It seems probable that the experimental method will make it possible to define more clearly the factors that determine the successful exploitation of this method of prophylaxis

Cotton Dust Asthma'

The disabling chest trouble due to the inhalation of cotton dust by certain workers in the cotton industry takes the form of attacks of cough or breathlessness occurring particularly on Monday morning after the week-end break. Gradually the symptoms spread over the ensuing days of the week and clinical examination of patients with established symptoms reveals the signs of chronic bronchitis and emphysema The death rate from bronchitis among male cotton strippers between the ages of 20 and 60 is five and a half times greater than that for all occupied and retired males and ten times greater than that in such dusty occupations as cement workers and lime burners Prof. Carl Prausnitz working in Maitland's department in the University of Manchester has investigated this problem He was able to show that although much has been done by mill owners to reduce the dust in card rooms the most dangerous fraction of cotton dust consisting of the particles under two microns in diameter still obtains access to the workers lungs the protein fraction of this dust contains some toxic factor which is probably responsible for the respiratory trouble Prof Prausnitz is not hopeful that desensitisation will improve the condition and since the present methods of ventilation and exhaust do not entirely exclude these minute particles the solution probably depends either on the adoption by the workers of suitable respirators of which a more satisfactory form is being sought or on the application of new means of preventing the particles from entering the air

Tuberculosis Treatment by Artificial Pneumothorax

The fate of patients receiving artificial pneumothorax treatment under the tuberculosis scheme of the London County Council between the years 1920 and 1930 has been reviewed by Dr F J Bentley

As a result of this study it emerged that those patients in whom complete collapse had been produced had a much higher rate of survival than those whose affected lung was only partially collapsed; also that success is more likely in the early stages of disease and where only one lung is affected It is interesting that favourable results in both sexes were found in the age group 25–30 while the age group 20 2 is peculiar in showing the best result in males and disappointing results in females Dr Bentley suggests that the treatment might well be used more extensively in young male adults

Artificial pneumothorax treatment is of limited application but in properly selected individual sufferers it sensibly increases the expectation of life and working capacity

Tropical Medicine

The concluding paragraphs of the introduction to this report record the formation and proposed activities of the new tropical medical research committee This committee has already made recommendations, on which the council have begun to take action, for the recruitment of able young investigators willing to work in the tropics and for the eventual establishment of permanent posts for research in tropical medicine, to which workers engaged at first on a temporary basis may reasonably aspire

In addition to launching this main scheme of fellowships and appointments, the council are prepared to assist research in tropical medicine in other ways as opportunity may offer In particular, grants will be available to enable workers in established positions at home, particularly those not having the facilities already possessed by the staffs of schools of tropical medicine, to make short visits to the tropics for the purposes of research or the collection of material

---

AIR-RAID WARDENS

THE Air Raid Precautions Department of the Home Office issued last week a memorandum explaining the need for an organisation of citizen volunteers to perform a number of important duties in time of air attack, thereby augmenting and relieving the normal resources of the civil authorities and safeguarding the general public These volunteers, to be entitled Air Raid Wardens, would work in contiguity to their homes and places of business, their chief duties being to advise their fellow citizens on the precautions against air raids as officially recommended, in time of war they would know how to start relief measures and where to apply for appropriate help

THE DUTIES OF THE WARDENS

The wardens will require organisation and training and it is proposed that their work would always be done in consultation with the police It is expressly stated that they would be males, and that no direct responsibility for fire fighting will be laid upon them, as an auxiliary fire service will be formed by the fire brigade

The qualities and functions of a warden are set out succinctly in the memorandum He should be a responsible member of the public, well known and respected in his area, and his duty will be to supplement the resources of the police and fire brigade by rapid information as to the details of the fall of bombs, and by giving immediate warning of the suspected presence of gas It would be his duty to shepherd the public to shelter when an air raid warning has been received, and to deal with casualties or damage until skilled help arrives Lastly and most importantly, the wardens are urged to set an example of coolness and steadiness among their neighbours In each borough or district they should form a service of their own under a chief warden assisted by head wardens acting as group leaders

The distribution of civilian respirators will be in the hands of the wardens acting in collaboration with the local authorities It is recognised that the services of a considerable number of trained men intimately acquainted with the particular locality will be required, for in any immediate preparations for war members of existing public services might not be available Although the war duties of the wardens do not commence until the actual air attacks, the respirators should by that time be already distributed

THE WARDENS IN TIME OF WAR

It is proposed that the wardens should operate from fixed posts, each man being responsible for a defined group of streets, or "sector," and each post should be manned during a raid by two or three wardens The duties of the wardens, as set out, may be more particularly summarised thus To know the organisation in their locality, to advise persons in the street when an air raid warning has been given, and to report at prescribed places the presence of gas or fires and the falling of bombs in their sector Other duties are to estimate the extent of damage done and to be ready to report upon it, to assist occupants of damaged buildings to find new shelter, to guide the police, fire brigade, first-aid parties, and rescue parties on arrival upon the scene of damage, to convey messages or render any other assistance required by police or fire brigade officers, and to help householders or the personnel of fire posts to fight incipient fires, pending the arrival of the fire brigade And to assist in every possible way to prevent panic The Government will be responsible for equipment, and wardens, after training, will be eligible for the Air Raid Precautions badge

ORGANISATION OF AIR RAID WARDENS

There are many points yet to be determined before the Home Office plans can be regarded as complete, but alternative schemes of organisation are put forward Every scheme of organisation should provide for a chief warden in executive control assisted by head wardens in charge of groups of posts These leaders will be required whether the control of the wardens is placed in the hands of the chief constable or of some other local official. Subject to this general principle, the scheme of organisation of air raid wardens can take one of several forms, of which the following are the main types —

SCHEME A

Air raid wardens may be organised independently of the police, under the control of some local official other than the chief officer of police They would work under the chief warden, who would be in executive charge of the service in the local air raid precautions organisation, but responsible to the permanent official deputed to exercise supervision and control If this scheme is adopted, it is nevertheless recommended that the police should be consulted before the actual enrolment of wardens, to ensure that only suitable men are chosen This scheme will be adopted in the metropolitan police district because it is felt that the size of the district and the large number of important local authorities which it contains make it preferable to decentralise the air raid wardens' organisation It does not follow that it would be the most suitable scheme outside the metropolitan police district Where this scheme is adopted, it would be possible to employ some existing body or association as the agent for organising and training the air raid wardens, the chief warden being a responsible official of that body or association.

SCHEME B

An alternative scheme would be for local authorities to arrange the framework of the wardens organisation particularly as regards the numbers of wardens required and the location of their posts on the basis that in time of war they would operate under the control of the chief constable Each area would have its chief warden appointed by the local authority or authorities concerned in consultation with the chief constable, and the chief warden would be responsible for the recruitment and training of wardens with such assistance from the police as might be arranged This scheme is of a hybrid character but it is not considered that there need be any difficulty in its working smoothly, provided that close coöperation was maintained with the chief constable from the outset, and it might be suitable for parts of county police districts It would be possible here to utilise existing bodies or associations as the agent for obtaining and training individual wardens.

SCHEME C

Under Scheme C the responsibility for framing the organisation of the wardens in peace time as well as exercising control in time of war could be entrusted directly to the chief officer of police This scheme is particularly suitable for adoption in boroughs having their own police forces.

THE RESPONSIBILITY OF LOCAL AUTHORITIES

The functions of the wardens will be essentially local but the responsibility for initiating organisation should rest with the borough and district councils, and in deciding between the alternative schemes of organisation as set out above the chief constable of the county should be consulted. It is not considered essential that the same scheme should be adopted in all parts of the country although it would be inconvenient if any county became a patchwork of diverging schemes and here the suggestion is made that a conference of local authorities in the county or parts of the county the chief constable being present, would serve to secure practical agreement Whatever scheme of organisation is adopted the wardens should be treated as a distinct service but where organised under a chief constable the control would involve more work than could be borne by the police force; and while the chief constable or the senior police officer in the area would have the control a chief warden with special staff would be necessary to do the detailed work under him.

TRAINING FOR AIR RAIDS

The memorandum adds details as to the executive control of local schemes the distribution of the wardens posts and the numbers required and concludes with advice in respect of the training of the wardens for meeting air raids This it is said should cover the following subjects —

(*a*) A general knowledge of the local air raid precautions organisation.

(*b*) A knowledge of anti gas precautions.

(*c*) A detailed knowledge of the scheme for distributing civilian respirators in their particular sectors, when that scheme has been drawn up and of the sources for obtaining replacements in time of war

(*d*) A detailed knowledge of their duties: (i) in advising and assisting the general public in matters of air-raid precautions generally (ii) in assisting the local air raid precautions services and (iii) in reporting damage to the proper centre

Wardens it is added should be fully conversant with guidance issued by the Home Office to householders generally and should be able and ready to advise the inhabitants of their sectors both in peace and in times of emergency on points connected with home precautions, or any special instructions issued—e g removal of people from unsafe areas

---

REMINISCENCES OF PAVLOV —Stories and incidents from the life of the Russian physiologist I P Pavlov as told by his associates and pupils to Prof K. S Koshtoyants of the All Union Institute of Experimental Medicine in Moscow will shortly be published by the Academy of Sciences of the U S.S.R in book form. Dealing with the period 1870 to 1905 the book will give a glimpse of Pavlov s early scientific work the methods he elaborated for studying the physiology of digestion and of the activities of his laboratory The Academy is also preparing for the press an academic edition of the complete works of Pavlov edited by Academician Orbeli

BOURNEMOUTH

CONFERENCE OF THE BRITISH HEALTH RESORTS ASSOCIATION

THE keynote of this conference held at Bournemouth on March 12th–14th was the need for more knowledge of climates At the opening session when the Mayor of Bournemouth took the chair a discussion took place on

Wintering in England

Lord HORDER pointed out that weather was not the same thing as climate; for that reason there were many advantages of wintering in England irrespective of whether the sun shone or not Exact knowledge about climate was not available to guide a doctor in his recommendation of choice of resort he could not be sure what air would suit a patient Lord Horder felt that the doctors of the resorts should get together and pool their knowledge in order to help those who were trying to cater for the invalid. Speaking more widely of health resorts in winter he said that the availability of sea water was of great importance and deserved attention Shelters and covered walks could be provided against the weather Great Britain was unique in its capacity to produce raw products but too often spoilt them in the cooking the old English inn must have been a roaring success and he did not see why the English hotel should not be as good as the continental one There had almost come to be an amenities front and he wished to see it kept at the best In particular attention should be paid to safeguard against noise There was the rowdiness of the adolescent and the deafness of old age but there were people whose appreciation of a health resort depended on the care spent in controlling noise; there were so many stresses and strains in modern life that could not be escaped why put up with that of noise when it could be dowsed? The noisy waiter should be eliminated as noisiness was infectious and spread.

Sir JAMES MARCHANT said that a thousand years ago an early visitor to Bournemouth had been Sweyn the son of the King of Denmark who came for three successive winters and had to be heavily bribed each time by the King of England to go away No country had so many types of scenery in so small a compass as England; were the health resorts doing all they could to preserve their natural qualities? The ironical thing was that the vandal knew a beauty spot when he saw it The resorts should have belts reserved for bungaloid fungus and slabs of flats and any vandal wanting to put up a building without an artistic architect s supervision should be made to choose a site in that belt The architects might hold licences and lose them if they permitted an eyesore outside the belt Noise and ugliness should be segregated The individualism which now marked the business of the health resorts should develop into a coöperative effort of all sections to plan the future of British resorts The medical profession might discover other ways of making greater use of them. The first line in the national defence was public health and our health resorts should be held in trust for the nation; with the coming change in age distribution there would be a vast increase in the numbers of potential customers

Dr K R COLLIS HALLOWES said that the majority of English people could winter in England more comfortably than abroad and with careful selection resorts could be found to meet all needs Some thought that an equable climate made a resort by itself, but for therapeutic success man's forethought was needed too In this country much more knowledge of climatology was required The medical men of the resorts should get together as the doctors at the inland spas had done and with the help of municipal authorities the resorts should combine in research work It was sometimes assumed that the suitability of a marine resort for winter residence could be decided by comparisons of the tables of meteorological figures and by digesting the attractively phrased literature issued by publicity departments, but these could not determine the reactions of an individual to a climate At some only of the marine resorts the meteorological station was under the supervision and control of the meteorological office Other records taken might have little value, giving "pocket climate" averages not comparable with those distinguishing other resorts Even at controlled stations along the coast, readings were taken under different conditions and were often not comparable Thunderstorm statistics were not always based upon official definitions but upon the opinion of the observer At present the figures recorded for ultra violet light were of problematic value, as the method used was not recognised by the Meteorological Office and the recording tubes were likely to be differently read by different observers Then, the invalid wanted to know what happened during the "invalid's day" between 9 and 5 rather than during the night, but the present methods of recording seldom indicated the humidity or the duration of frost or of rain between those hours Resorts should develop differently according to their amenities, and should cater for all weathers, there should be provision of social centres, clubs, indoor swimming pools, cheap transport between beach and apartments, combined season tickets for admission to municipal amenities, and ample facilities for sports Many winter visitors would prefer simple cooking, especially more attention to vegetables and more choice from pork on Sundays Medical practitioners had recently been urged by the British Medical Association to seek election to town councils, on grounds that such representation would be beneficial for the profession, the town council, and the community At winter health resorts such representation should ensure greater efficiency in development and strengthen the "Wintering in England" movement The marine resorts had in sea water unlimited supplies of a natural mineral water of known therapeutic value, which was entirely suitable for all bath, douche, and other methods of external treatment

Sir John Atkins said his impression was that some patients should winter abroad if they could afford to but the perils of the journey should be remembered exposure during the crossing and bother at the customs were examples It was better for some patients to winter in England but the resorts must pay attention to the needs of the patient and his friends He read a letter from one patient saying, "I'm sure you have no idea how deadly dull it is here" Abroad there were plenty of opportunities for recreation and the English resorts which did not cater, as Bournemouth did, for the visitor might as well be ruled out as far as wintering in England was concerned

Sir Archibald Weigall mentioned the enormous improvement in foreign spas and resorts in the last few years Other reasons for going abroad were the escape from the commercial atmosphere of the patient's ordinary life and the attraction of the recreation of gambling He mentioned the restriction imposed on English hotels by the licensing laws and said that the overhead charges due to legislation relating to employers and employees made cheaper and better accommodation impossible

Dr G de Bec Turtle had found that if patients felt they were at their best on their native heath they should be sent to the resort nearest to it

Dr W Asten stressed the importance of taking accurate meteorological readings and of putting them on a uniform basis

Dr Alfred Cox thought the hotel industry was unfairly treated by legislation, charges had to be high in consequence

The Mayor of Poole mentioned the great importance to health resorts of attracting not only visitors but also suitable residents, for example the retired Britons returned from the colonies

In the afternoon session, when Dr S Watson Smith took the chair, the subject of discussion was the

Curative Action of Sea Climate

Prof Otto Kestner, M.D, said that the gain in health and vigour obtained by living for some weeks by the sea was a matter of common medical experience In order to find out the mechanism of this peculiarity of the sea he had carried out investigations at the health resort of Wyk on the Island of Fohr in the German North Sea, on adults and children He had found that healthy adults showed very little reaction to changes in climate, but children, both healthy and ailing, reacted more and so were better for observation In them he had noted many changes The oxygen consumption was increased at the seaside as it was also in the Alps, and in both places this increase in metabolism was associated with retention of nitrogen Thus there is implied a building up of new tissue and that had been observed in adults and children, the circumference of the arms and legs definitely increased, that of the abdomen diminished The level of nitrogen excretion fell below that of the intake during the stay at the seaside, returning to normal when the children went home ,The curve of growth of the children similarly took an upward turn when they went to the sea and continued in a course parallel to its former gradient only on their return

At first he had found a correlation between the hours of sunshine and the increases in hæmoglobin and red cell count, but that was when the children went down to the sea only on sunny days, when they were sent regardless of the weather it was found that cold wind and fresh air had the same effect as the sunshine The stimulus of the sea increased the secretion of gastric juice, which he had measured by means of test meals, the hydrochloric acid content was higher and was not further increased by histamine, suggesting that it was already maximal A stay on the sea shore seemed to be a better way of increasing secretion than giving histamine The movements of the stomach were accelerated and even the finely regulated system of the blood sugar curve was not quite the same by the sea as in hospital There was no danger in satisfying the greater appetite even in people with low specific dynamic action who were inclined to grow fat, because the raised metabolism protected against that The increased appetite at the sea was very valuable for many of the children A good proportion of them were under nourished and for that reason had poor appetites, such children did not eat enough, even if the supply of good food was provided by parents schools or charity The action of the sea air was then of the greatest use in breaking a vicious circle.

The place of action of the sea climate was the skin. Humans differed from other mammals in being naked an attribute only recently acquired in the scale of evolution Many animals regulated their temperature by adjusting their combustion in the liver and elsewhere in man alone the adjustment was made by dilatation and constriction of the capillaries of the skin. If a man were cold his capillaries contracted down leaving a relatively avascular skin and layer of subcutaneous tissue which served him as an overcoat This was the best method of thermal regulation excelling any found in animals but was liable to be lost owing to our way of living Prof Kestner had examined the reaction in the children by touching the skin for three seconds with ice and timing the change from whiteness to reddening in the skin In healthy children this took only two seconds but took five in convalescent children before their stay at the sea As the results of the stimuli of the sea sun cold air and cold water the capillaries of the skin learnt their gymnastics again and the children could bathe in the sea and play naked in the open air even in winter time, without a decrease in body temperature The children in the convalescent homes at Wyk were in the open air for not less than four hours daily and twice a day for from five to thirty minutes naked even in winter the children liked it and were unhappy if forbidden to join in the capillary gymnastics The skin reactions were also sometimes sluggish in those with high blood pressure It was a rule of pathological physiology that a good remedy worked more energetically on the pathological than the normal organ. Curschmann who was continuing the observations had found that the blood pressure was not altered in normal people by sea bathing but was lowered in those with high pressure It could be decreased for a considerable time by repeated sea bathing in patients who had no anatomical alteration of the vessels. Curschmann had called the sea-shore the hypertonic s paradise

In conclusion the speaker emphasised that the stimuli of the sea shore could only be effective if the patients exposed their skin to them and there was no sea climate in the sheltered rooms of homes and hotels. When the doctor could adjust the dose to the individuality of the patients the sea climate was a powerful remedy

Sir WALTER LANGDON BROWN quoted Dr Leonard Williams s dictum that To prescribe change of air with intelligence it is necessary to have some knowledge of climatology to prescribe it with success it is essential to have some acquaintance with different localities He had often been asked by patients to recommend a climate which was warm dry and equable to which he replied that they might find it in Heaven but that they would not do so on earth The moisture in the air was a potent factor in maintaining an equable temperature in a dry climate the temperature was of necessity liable to considerable fluctuations and on the high veldt in South Africa he had seen a mirage at three o clock and hoar frost by half past six Such a climate however stimulating to those who were well was trying to those who were in poor health. Man had been described as an automatic thermostat but the maintenance of a constant temperature imposed a tax on the heat regulating centres and on the heat producing structures in the viscera The importance of rest in the treatment of febrile tuberculosis was clearly recognised It was also true that a fairly constant environment saved effort on the part of the heat-regulating mechanism, a fact of importance for those suffering from physical or nervous exhaustion

The seaside could not claim to offer a panacea in the way of climate gouty subjects usually did better at an inland resort. Some with paroxysmal neuroses did not do well though in this respect as in so many others the asthmatic expressed his idiosyncrasy Bracing marine climates were not always suited to cases of insomnia, but he had found, like many tired or neurasthenic patients that Bournemouth increased the natural capacity for sound sleep For chronic bronchitis and emphysema the conditions provided at Bournemouth by equable temperature humidity and pine-laden breezes were admirable. The treatment of bronchiectasis had passed into a more active stage in which the surgeon participated, but for the convalescent after his somewhat drastic handling Bournemouth could offer many advantages Heart diseases had been mentioned as an indication for treatment in the district, but the category should not include those with any suspicion of active rheumatic carditis The group called the diseases of civilisation—hyperthyroidism diabetes hypertension and peptic ulcer—were all becoming commoner with the increasing pace of civilisation To those might be added what Crile called neurocirculatory asthenia generally due to emotional causes operating through the sympathetic nervous system; this had been treated by denervating the adrenals which seemed like jamming on the brakes because the engine was running too hard He would prefer to change the environment and mode of life to quiet the engine down For all conditions where the kinetic drive of modern life had been too much for the individual he found reasons why a marine climate of the type provided at Bournemouth formed a useful and helpful part of treatment

Dr S WATSON SMITH reviewed the outstanding characteristics of marine resorts of the east and south coasts of Great Britain and said that the recommendation to be made to a patient depended much on the nature of the case As a rule the climate should be an equable one usually in a coastal town The medical profession now recognised that our own coastal resorts belonged to the most health giving in the world and that they could be used by the patient with greater likely benefit than any abroad It seemed logical that an invalid should find a climate akin to that of his native air preferable to any foreign one; in addition there were here no language difficulties no insuperable dietetic obstacles no overheated rooms no un English entertainments, no long tedious journeys there and back and no long distance separation from home and relatives Bournemouth could boast of a number of climates so that some choice might be made of the district for the patient whether near the centre of the town or in one of the several chines or in the north of the town or on the uplands behind. Plethoric people and those with high blood pressure did well in that relaxing climate (using the word relaxing in no derogatory sense but as meaning sedative) so did those with insomnia Rheumatic fever and acute articular rheumatism were practically unknown in the district, and this fact seemed a powerful argume establishing a hospital or home for rheumatic Rheumatoid and osteo arthritis were difficult to arrest in that climate other hand was best treated at a bladder was seldom met with disease of the kidneys or repeatedly found to benefit b

Dr A G S **Mahomed** suggested that the old medical classification of phlegmatic, sanguine, and other types might now be explained in terms of hormonal variations and might serve as a basis for explaining the different effects of climates on individuals

Hospitality

In the evening the Mayor of Bournemouth entertained the delegates to dinner at the Pavilion Dr W **Asten** proposed the health of the Association, saying that throughout its life it had been an advocate of British health resorts, not only in summer but all the year round He congratulated the Association on its handbook Marine climatology had been much neglected mostly because a sufficiently important place had not been found for it in the medical curriculum. Doubtless that error would be corrected when excessive interest in physical medicine, nutrition, and the vitamins waned He liked to think of the tripartite coöperation of the medical profession, local authorities, and the State, but it should stop at the point of federation He was sure that a complete State medical service was contrary to the country's ultimate welfare It might conceivably even intensify the amount of self drugging among the public, for mysticism and superstition still existed, on the other hand the medical profession sometimes took itself too seriously and its advice was disregarded with the result that the patient got on very well.

Sir **Walter Langdon Brown** replying, regretted the loss during the year of Colonel Elliot, he had been a good conjurer and his greatest feat had been to make the British public proud of its health resorts The attractions of foreign resorts were the three “W's” the weather, welcome, and wine Characteristically the foreigners advertised their good weather, the English only their bad Anyone receiving a better welcome than that of Bournemouth was lucky The wine cellar was certainly a difficulty, but the restrictions on currency abroad were much more irksome to him.

Sir **Archibald Weigall**, proposing the toast of the county borough of Bournemouth, said that legislation had never distinguished between pleasure and health resorts, the latter should be entitled to privileges by holding certificates from the Ministry of Health The tendency of the day was to pour out legislation for the local authorities to administer The measures unfortunately brought the rough and tumble of party politics into local affairs, he hoped the local authorities would not lose their individuality

The Mayor of Bournemouth, responding, said that the town's reputation had been built up as a place of health and recuperation from the earliest days The impression still lingered from past times that holidays were cheaper abroad. The Association had done much to tell the public that they could get as good and as cheap a holiday here as elsewhere Bournemouth hotels were as good as any He thought many went abroad to avoid the petty and irksome restrictions which amazingly existed in spite of democracy

The delegates made a tour of the town on the last day

Hospital Amalgamation at Bristol.—The governors of the Bristol Royal Infirmary have decided upon amalgamation with the Bristol General Hospital The amalgamation is, it is stated, unanimously supported by the committees of both hospitals

MEDICINE AND THE LAW

Motorist and Insulin

There were doubts on the law as well as on the facts in a case at Bow street police court last week. Charged with driving a car “while under the influence of drink to such an extent as to be incapable of having proper control,” a motorist said that his condition was due not to alcohol but to a double dose of insulin taken on an empty stomach The learned and experienced magistrate is reported to have remarked that it was clear that in the next Act of Parliament such people should be included with those under the influence of drink and unfit to drive But are they not already included? The words in the Road Traffic Act are “under the influence of drink or a drug” Is not insulin a drug? There is nothing in the Act to indicate that the drug must be an illegally administered narcotic The motive for taking the drug is immaterial, the Act is concerned merely to forbid motorists driving when they are not in a proper condition to drive The magistrate went on to state something of great importance “A motorist under the influence of an overdose of insulin is,” he said, “from the public point of view an equal danger to one under the influence of drink.” If so, we may infer that the police might have secured a conviction by charging the motorist with having taken a drug It is not the law which needs to be altered, but the form of the charge

The facts stated for the prosecution were that there had been a collision in Gerrard street The motorist was said to have turned out of Macclesfield street and to have collided with a stationary car A policeman said he found the motorist unsteady on his feet and smelling of alcohol, on the way to the police-station he became violent, when two policemen got him as far as Piccadilly he refused to go any farther and sat down in the road The police surgeon said that the accused told him he suffered from diabetes and had taken a double dose of insulin and had had no food. The witness agreed in cross examination that the effects of a strong dose of insulin would be light headedness, irritability, clumsiness in moving the limbs, and perspiration, persons in fact, who have taken alcohol and persons who have taken insulin exhibit certain common symptoms The magistrate observed that there must be some doubt whether the man's condition was due to alcohol or to insulin The case must therefore be dismissed The police, it would seem, in future cases of this kind will have to make up their minds whether to charge the taking of drink or the taking of a drug Whichever charge they select, they must be prepared with evidence to remove the doubt which last week was fatal to the prosecution

Negligence Alleged against Mental Hospitals Board

The protection which medical practitioners and others believed they had been granted by Section 16 of the Mental Treatment Act, 1930, has been invoked in vain by the Lancashire Mental Hospitals Board and two of its officers in a case which was taken to the Court of Appeal Mr and Mrs Holgate of St Anne's on Sea are plaintiffs in an action arising out of injuries inflicted on Mrs Holgate by a patient who was let out on licence from the Calderstones mental institution They allege that the board and the officers concerned acted without reasonable care in allowing the man to be at large Section 16 bars their claim unless they obtain the leave of the High Court; leave is not to be given unless the court is satisfied that there is substantial ground for the contention that the proposed defendants have acted in bad faith or without reasonable care The plaintiffs application for leave came before Mr Justice Talbot. One of their allegations is that the officer who ordered the release of the patient had no power to do so The judge granted leave and the three judges in the Court of Appeal have unanimously declined to interfere Lord Justice Greer observed that Mr Justice Talbot was right in holding that there was substantial ground for the contention that the defendants acted without reasonable care whether that contention will prevail at the trial I cannot say'

It will be recalled that Section 330 of the Lunacy Act of 1890 contained a weaker safeguard Persons responsible for the certification of a lunatic were not to be liable to civil or criminal proceedings if they had acted in good faith and with reasonable care: proceedings could be stopped by the court if the court was satisfied that there was no reasonable ground for alleging want of good faith or reasonable care. The startling results of the Harnett litigation and similar cases led to the change in 1930 whereby the burden was placed on the plaintiff in the terms already cited instead of it being for the defendant to invoke the safeguard by proving no reasonable ground' Section 16 of the 1930 Act has been of considerable value and the grant of leave thereunder has been rare The trial of the Holgate case will evidently be of considerable interest

VIENNA

(FROM OUR OWN CORRESPONDENT)

TULARÆMIA IN AUSTRIA

In a paper recently read before the Vienna Veterinary Society Prof David of the Veterinary University discussed the problem of tularæmia. This disease had become known in 1906 when after the great earthquake in San Francisco cases were observed which resembled plague and which were also noticed in animals especially rodents and wild rabbits In Austria the first case was reported in 1935 The chief symptoms were conjunctivitis and lymphadenitis and soon afterwards another case was observed in the eye clinic Both patients had handled diseased hares and jack rabbits Within the last four months over 200 cases have been reported from all parts of Austria the majority coming from a country district not far from Vienna Males were attacked much more often than females the ratio being 70 to 30 The cases differed in no way from those reported elsewhere There is an ulcero glandular type when infection occurs through contact with an infected rabbit or other infectious material and an ulcer appears on the finger or hand as the primary lesion, with enlarged gland In other rarer cases only glandular swelling is noticed often combined with conjunctivitis (the oculo glandular type) without the primary ulcer but the glands tend to break down later producing the secondary lesion It is not quite sure whether infection by insect bites has occurred in this country Treatment consists largely of rest good feeding surgical drainage of suppurating glands, and general symptomatic care In America a special anti tularense serum (Foshay's serum) has been used with apparently good results Laboratory tests show a specific agglutination which appears in the second or third week of the infection. The disease is followed by a lasting immunity It is very easily transmissible and highly infectious in spite of the rubber gloves overalls face covers and cellophane eyeglasses which are used in the laboratories one person assisting at a post mortem was infected recently in Vienna Prophylaxis necessitates the strictest cleanliness in handling living or dead rodents Animals found dead are to be regarded with extreme suspicion In view of the economic importance attached to this matter compulsory notification of all cases observed in man or animals is urged by Prof David.

A NEUROLOGIST HONOURED

A few days ago the eightieth birthday of that eminent authority on diseases of the brain and the nervous system Prof Wagner von Jauregg the discoverer of the malaria treatment of general paralysis of the insane was solemnly celebrated by the Austrian Society for Neurology and Psychiatry Representatives of the Government the University and of numerous learned societies at home and abroad were present and paid homage to the scientist who was himself prevented by ill health from attending. The president of the society Prof Otto Pötzl the successor to Wagner Jauregg as chief of the clinic described how just 50 years ago Wagner-Jauregg conceived the idea of artificial hyperpyrexial therapy having observed that an insane woman showed considerable improvement after an attack of erysipelas It took him 30 years before he could fully work out all the details of his method in 1917 It is interesting to note that in this instance the discovery had its origin in observation and experience the theoretical foundations having been laid down later by Hoff and Silberstein They showed that just the malaria infection produced an increase of the antisyphilitic qualities of the blood and brain tissues whilst typhoid or tuberculous infection which were also tried against syphilis gave no satisfaction Prof Pötzl also called the attention of the audience to the remarkable fact that the original strain of *Plasmodium malariæ* which Prof. Doerr had placed at Jauregg's disposal in 1917 was still alive and active after having undergone 481 passages through human hosts The study of its peculiar variations and alterations in itself was an important contribution to malarial research Prof. Pötzl went on to describe Wagner Jauregg's other great discovery which has largely contributed to the successful fight against goitre and cretinism in the Alps On Wagner-Jauregg's advice ordinary salt was charged with a minute quantity of iodine (1 mg per kg salt) and thus sold to the population of the districts in the Alps affected with hypothyroidism The results are most gratifying. It may be just mentioned that Wagner-Jauregg has been awarded the Nobel prize for medicine for his discovery of malarial therapy and a gold medal commemorating his work has been struck and presented to the Vienna Neurological Clinic which will henceforth be known as The Wagner Jauregg Clinic.

VON SCHRÖTTER'S CENTENARY

The second person whose work has recently been honoured by the celebration of his centenary is Prof Dr Leopold von Schrotter who died suddenly in 1908 He was an eminent scholar in materia medica but his chief importance for medicine and for Vienna was the fact that it was he who brought laryngology—then a new branch of medicine—to the level of a recognised specialty His efforts succeeded in instituting a special clinic for laryngology in Vienna, the first of its kind in the world. His genius and his splendid qualities as a research worker made him, entirely self taught in this work, a great authority on diseases of the larynx and trachea The other side of Schrötter's life work is connected with the fight against tuberculosis It was due chiefly to his incessant endeavours that the system of sanitorium treatment and open air therapy was introduced to the then existing Austrian Empire Tuberculosis of the respiratory organs at that time was termed here "morbus Viennensis" A statue of Schrötter, which has been placed in the Hall of Honour of the Vienna University, was unveiled on his centenary in the presence of the leaders of science and of the government

GRAINS AND SCRUPLES

FROM A RUSTICATING PATHOLOGIST

IV

No one that I have asked has been able to tell me who invented the idea of tarring roads It was a very great discovery, worth a peerage and a fortune as well as the preservation of a name, as anyone knows who remembers what the dust nuisance was like just about 30 years ago, when you had to get off a bicycle after passing an automobile because you could not see and when main roads were bordered with empty houses in which no one would live if they could help it Knowing what we do about the delay between the beginning of an irritation and the appearance of a tumour in mule spinners and shale workers, it seems possible that this dust may have had something to do with the increased incidence of cancer of the lung in recent times, asking pardon of those who do not believe that there has been any increase Various things were tried, hygroscopic salts such as calcium chloride and so on, but tar was evidently the real solution, though it was not at first very popular because relatively few people had cars and many had dogs which enjoyed cleaning their feet on the drawing room carpet or the spare room bed Blatant utility is no royal road to fame as the improvements in medicine show I do not suppose that any drug has contributed much more to human happiness than aspirin, there are many which are more indispensable and do much more to save life, but from the consumers point of view there are very few that are of so much use to him in getting through the changes and chances of his life But I have no idea of the name of the man who brought it into use (which may of course be just ignorance) and Einstein is better known to the general body of people who eat it Nor is aspirin celebrated when orations are made about the progress of medicine There are I expect several reasons for this One is that while the patient wants chiefly to be comfortable, the doctor wants to make him well and keep him alive Another is that medicine always has been and still is a learned profession and discoveries are valued for being rational, for fitting into and extending the scheme of knowledge, as well as for being useful Banting's discovery of insulin was rational a dog without a pancreas has diabetes, if the duct is tied the secreting tissue disappears, the islands of Langerhans survive, and the dog does not have diabetes, therefore there must be something in the islands which prevents diabetes And it was so, though curiously enough the use of insulin has turned out to be empirical, for there is no agreement yet as to how it works Lister's discovery of antiseptic and aseptic surgery was thoroughly rational So is Rosenheim's mandelic acid the rational result of a deliberate search for a substitute for the oxybutyric acid of the ketogenic diet Liver for pernicious anæmia was partly rational and no more could be expected, since it was only by its use that the nature of the disease was revealed But aspirin is about as rational as sarsaparilla and it suffers in estimation accordingly

* * *

Our local paper has just published a reprint of its first issue, which came out on Jan 28th, 1837, to maintain "the real liberties of the People consistently with due reverence for the law the preservation of the unimpaired establishments of the Church, the maintenance of the just prerogatives of the Monarch, and of the privileges of the Hereditary Aristocracy of the land" Under such auspices one can hardly suspect the extraordinary value of Woodhouse's Balsam of Spermaceti or Pectoral Cough Drops, one dose of which, the advertisement says, will relieve "most affections of the chest and lungs in ten minutes" and as a guarantee of good faith "persons doubting the efficacy of this medicine may take a dose in the Proprietor's shop before they purchase" The balsam was peculiarly valuable for the prevailing epidemic of influenza which led to the ball at the Subscription Rooms being very thinly attended despite a sumptuous supper, and to "awful and horrid" scenes when attempts were made to bury several hundred people in a day in St Pancras graveyard I wish I could say that the paper also records an exceptional mortality among the local polecats but nothing so interesting can be found, and the cause of the epidemic is held to be "no mystery" since it was plainly due to a sudden change in the atmosphere "from great dryness to great humidity, both states being accompanied with a severe depression of temperature" But how proud Mr Decimus Woodhouse must have been to have a pectoral cough drop which would cure it in ten minutes—if only the public would take it Does the recipe still survive? For we still lack such a certain cure

* * *

Nor do we yet know how an influenza epidemic comes about The definition of the virus which has an ætiological relationship to the disease has given us a great deal of pleasure—æsthetic pleasure at a particularly elegant piece of work and carnal pleasure at the prospect of a vaccine—but it has introduced great complications into the epidemiological problem To relate epidemics to the weather and the seasons as such had a stately simplicity about it which was and still is attractive, and the necessary sensationalism was to be had out of earthquakes and other paroxysms of nature If children's diarrhœa began to be serious when the 4 ft earth temperature had reached a certain level—well there it was, a delicious piece of information for the curious and singularly deterrent to any practical action. When Dr Johnson and Mr Boswell went to the Hebrides they heard a good deal about the boat cold at St. Kilda Johnson thought the whole thing was a sham and that the islanders went on coughing because they did not like visitors and did not want to talk. How mysterious it must all have seemed in 1773 and how satisfying the explanation that it was not the arrival of the boat at all which caused the catarrh but the north-east wind which was necessary for the trip from the mainland. But the parasitologists have changed all that We now have two sets of facts—the relation of epidemics to the weather and the season of the year (which are not necessarily the same thing) and their relation to the complicated interaction between the host (with its varying susceptibility and resistance) and the parasite (with its varying virulence and infectivity) Only for plague do we seem to have anything like a complete account Human plague depends on the abundance and activity of the fleas which transfer it from rat to man and it ceases when these are sufficiently depressed by the weather—by dry hot weather in India by a cold winter in England A green Christmas means a full churchyard may perhaps be a reminiscence of the disease which was for more than 300 years a major cause of death in this country In some other diseases—e g diphtheria—the host-parasite interaction is fairly well understood but the new discoveries have not yet been fitted on to the old facts that they are seasonal afflictions On the whole it seems likely that the immunity of the host is about the most cogent factor and that the spacing of epidemics may be determined by the accumulation of susceptible individuals either by birth (as in measles) or by the lapse of acquired immunity (as perhaps in influenza) But those who have had the luck to have been trapped into reading Creighton s History of Epidemics in Britain will know that there are other sides to the whole question. It is indeed a good thing that he was a heretic and did not believe that bacteria were the cause of disease but it would be better if someone who does believe in them could imitate his industry and scholarship and write a new edition; I wonder if the obvious man is doing it It would be something if we could know how much truth there is in the conclusion which was so clear in 1837 that cold wet weather causes an epidemic of influenza there are masses of modern data waiting to be analysed.

* * *

Which brings us by a natural drift of gossip to pass a word or two about the healthiness of different places and their climates When Cæsar landed in Britain he found civilisation at its brightest in the south-east, and it is the same to day And it is difficult to think that climate has had nothing to do with that amazing aggregation of 7 or 8 million people living closely packed together in the London area and leading healthy I hope happy and certainly productive lives The London climate is indeed exhilarating physically intellectually and spiritually and as usual it is impossible to disentangle body mind and spirit which all work together for healthiness, backed up as they are by a very efficient public health service In the summer it is about the hottest place in England and in the winter as cold as anywhere which is probably good for us though the excellence of its air depends chiefly on its being dry so that our skins evaporate quickly and keep cool. Going to the west is equivalent to putting on a rubber mackintosh and human vitality deteriorates as is seen in the relatively high death rates of purely rural areas in Cumberland Westmorland, West Wales, and the south west: Devon they say is no good to anyone between 4 and 40 In Cæsar's time the people in these places were probably still in the Stone Age and it is still true that the districts which are blessed with a good supply of really soft water to shave with lag behind the south-east in the maturation of human qualities The effect of damp air is of course like all environmental factors relative to the material on which it works. On any rational scheme Lancashire ought to be a very inferior place there are more people than in the London area (though not so tightly packed) and the climate is horrid especially in the summer That the inhabitants are what they are and do what they do can be due only to their almost preternatural qualities it is one of my few quarrels with fate that I was not born a Manchester quaker Apart from rheumatism for which all neighbourhoods are bad, places differ among themselves a great deal, and what surprises us is that people go on living in bad places when better districts are available As William James says, it is of course inherent in man to prefer life on any terms to no life at all but that is not actually the alternative offered to those who inhabit Central Asia Tierra del Fuego Arctic Canada and even Orkney which has, so the returns show 79 gales per annum or Derby where the sun seldom shines Emigration there has been in plenty but seldom depopulation The truth seems to be that most people, irrational as they are and ought to be, prefer the place they are used to and the mode of life which goes with it The locality for which they have the feeling that it is their own is for them the best which is perhaps why no author of a guide book can help turning his account into an argument that the district he is writing about is actually God s own country Mark Rutherford is exceptionally honest; when he is trying to make the best of Bunyan s country he can get no further than it has a wide sky and it is quiet, which naturally makes everyone want to go to Elstow and have a look at it

* * *

Amongst all the progress of medicine which has marked the 100 years of the local *Standard* the belief in the curative qualities of air seems to have declined and dying men have given up gadding about as they used to Knowledge of the world has shown that man can live very nearly anywhere without being very much altered; the north and south poles and the top of Everest seem to be just within or just outside his capacity Hence the view that how a man lives is more important than where he lives which is one of those improvements which have come from a better appreciation of the general nature of diseases. There has been a decline of the mystical view that a disease is something imposed on the body for which somewhere in the world a herb a stone an atmosphere or what not is to be found and with this a rise in the pathological outlook which sees that the body always tries and generally succeeds in curing itself and that a great deal may be done in helping incurably lame dogs over degenerative stiles. It seems to me as a patient who has spent a good deal of time in post mortem rooms that the improvements in diagnosis and treatment in my own time have also been very great though not I imagine any more than in other branches of human activity or in the preceding medical generation the patient now has a much better time than he used to have when there was no antitoxin for diphtheria and no anæsthetics for tooth drawing (at any rate for children) The whole business now is far more rational than it was, and the concentrated object of medical research is to make diagnosis and treatment a logical science But perfection in this aim is and will be as elusive as Major Road, and, speaking as a grateful patient, I was rather shocked to read in THE LANCET the other day that the conservator of the Hunterian Museum thought that the student should be well trained in the experimental method because he would find when he came to clinical work that diagnosis was conducted in the same way in Dr Beattie's Garden of Eden clinical data "when properly correlated and analysed according to the rules of the experimental method, lead to a conclusion as scientific as those of the investigator in a physiological laboratory" This is either bad experiment or bad medicine If an experimenter wants to find out what 2 and 3 add up to, it is obligatory on him to be sure that what he thinks is 2 really is 2, and that what seems to be 3 actually is 3 until he can be certain on these points it is entirely illegitimate for him to draw any conclusion about their sum if he cannot reach surety he must put the matter aside and tackle something else or take a holiday It has always seemed to me that the great trouble of the doctor is that he has to do sums with numbers which are often very uncertain and his great pride that he usually gets the answer somewhere near right If he failed to come to a conclusion adequate for action, he would be a bad doctor, if he drew a conclusion from such froward data he would be a worthless experimenter And, again as a patient, I judge that his first business is to be a doctor The clinician is indeed in the same predicament as Johnson was over his dictionary "to deliberate whenever I doubted, to inquire whenever I was ignorant, would have protracted the undertaking without end and perhaps without much improvement" And both parties have extricated themselves pretty well · to cure a patient without knowing what is the matter with him is no mean performance

* * *

Only in one particular does medical practice seem to have deteriorated The layman now takes more interest in and knows more about technical details, and he has become more critical correspondingly the doctor has put off some of his authority with his priestly vestments It is all to the good that the doctor should wear a soft hat, and the maintenance of good health, if not the cure of disease, is better attained by intelligent coöperation than by arbitrary rules indeed the whole sanitary progress of this country, from Chadwick and Simon onwards, has been achieved by inviting the public to behave in a common sense way rather than by orders from Whitehall. But with this gain there has also been some loss of confidence which is of no help to the patient One of the greatest—perhaps actually the greatest—service which a doctor can give to a sick man is to relieve him of all responsibility about his own conduct, and there is no more satisfactory asylum than a hospital bed. There is no more worry about what he shall eat or what he shall drink or wherewithal he shall clothe himself he is dressed and washed and fed *p r n*, nor need he concern himself about what is the queer tasting stuff he has out of a small glass, it may be nothing more than ritual but that does not matter That this resignation, this resumption of a baby's position, helps him to get well is simply a matter of experience which at the moment I need not try to explain Many of my friends are qualified, and I notice that the ones who are too intelligent about their own maladies and cannot forget themselves far enough to believe in a bottle of medicine, do not make the best progress when they are ill What they need is childlike faith (which is very far from being childish), and if they would only take advantage of their chance to retire for a while from this troubled world they might put it to good use Was not "Blood Pictures" written in hospital and did not Mark Clark learn all fours in a whitlow?

PANEL AND CONTRACT PRACTICE

Capitation Fee for Adolescents

ON March 11th Sir Kingsley Wood, the Minister of Health, who was accompanied by Mr Scrymgeour Wedderburn, the Parliamentary Under Secretary for Scotland, received a deputation from the British Medical Association, when Dr H Guy Dain urged that the fees paid to medical practitioners under the national health insurance scheme should be increased, and that the fee should apply not only to the present insured persons but also to the juvenile workers for whom the Government had announced their intention of providing medical benefit The deputation suggested that as on former occasions the matter should be referred to arbitration Sir Kingsley Wood said that he considered that a flat rate substantially below the present figure could well be justified

Replying to a question in the House of Commons four days later Mr Hudson, parliamentary secretary to the Ministry, said that the whole matter was to be referred to an independent court of inquiry

Medical Insurance Practice

London insurance committee is to spend £200 in issuing to each practitioner in its area a copy of "Medical Insurance Practice,' to which we referred *recently* In the report of the subcommittee which *recommended this action is a list of documents* issued to practitioners joining the medical list These include the medical benefit regulations, the National Formulary, the drug tariff, specimens of nine different forms, five memoranda on various subjects, a requisition form for stationery—in all 32 items, apart from the terms of service and the allocation and distribution schemes This avalanche of literature, primarily intended for the practitioner's *instruction* in the way to carry out his contract with the committee, is accompanied by no guide or index The subcommittee has visualised the perplexity of a practitioner new to insurance work, about which document he should *consult in relation to* a particular urgent problem with which he is faced

An Inadvertent Overcharge

An insured woman gave up work on marriage Shortly afterwards, in January, 1936, she needed treatment, and being under the impression that she was no longer entitled to it she did not, in applying for her doctor's services, represent herself to be an insured person She told the doctor, in fact that she had ceased insurance Towards the end of the year she again became ill and *obtained further* treatment as a private patient, paying an account amount in all to £1 In December, 1936, she received a notification from the insurance committee that her title to medical benefit did not terminate until the end of 1936 and realising her mistake she promptly applied for a refund of what she had paid Clearly *this was a case of genuine misapprehension as to the* insurance status of the patient —a misapprehension largely brought about by the insured woman herself assisted perhaps by the practitioner's omission to verify the removal of the woman's name from his list. Under Clause 7 (3) as it now stands the insurance committee can adjust the matter by *repaying the £1 to the insured person and deducting* it from the doctor's remuneration But the doctor will be the poorer by the value of the medicines he supplied

THE OVER TREATMENT OF GONORRHŒA

To the Editor of THE LANCET

"So they do nothing tis a venial slip —(*Othello* IV 1, 9)

SIR,—Modern methods of dealing with gonorrhœa in the male seem to be strangely opposed to the fundamental principles of treatment for other diseases It is some time now since as registrar *at the London Lock Hospital, I had large experience* of this condition As surgeon in charge of the genito urinary department of a teaching hospital I see it rarely for gonorrhœa has been withdrawn from the circle of hospital life and wedded to syphilis (an unhappy and incompatible match) and they live apart in a dark and uncritical world of their own

It is a common observation that acute urethritis subsides as rapidly as does acute catarrhal rhinitis if the patient do nothing but lie in bed Unfortunately social custom demands that gonorrhœa should be an ambulatory disease and this excellent treatment is seldom practicable When such rest cannot be given it is surely all the more illogical to irritate the inflamed mucosa by the active measures *so frequently employed It is an axiom that anti*septics cannot destroy gonococci in the urethra without damage to its lining membrane. Gentle irrigation with a mild solution washing pus out of the anterior urethra does no harm Frequently however it seems that posterior irrigation is employed from the start of the disease—an illogical procedure which unless carried out very efficiently is dangerous It is for most patients a difficult art and for some an impossible one to acquire In a recent case, as often before I have seen it responsible for an acute spread to the posterior urethra and an epididymo-orchitis. During the acute stage of posterior urethritis bladder irrigation is fortunately too painful to be possible In chronic stages of the disease when the posterior urethra is *already infected filling* and emptying the bladder from without with an antiseptic is more venial but I think compares unfavourably in efficiency and safety with the passage of large quantities of urine

Much misdirected energy is also devoted to massaging the anterior urethra and the prostate gland This form of treatment seems to be carried out too early too often and sometimes too violently When active inflammation has subsided and mucous collections are present in Littre's glands, prostatic ducts or vesiculæ seminales the occasional use of massage is probably beneficial Employed earlier in the disease it must be harmful or all our teaching of first principles is wrong Employed frequently (daily or even twice daily massage over a period of weeks is not uncommon !) it produces a traumatic irritation Some authorities demand that as a criterion of cure the urine should contain no pus cells even after vigorous massage of the anterior urethra and prostate gland on a full-sized bladder sound This seems to me a queer test of normality Surely no urethra unless tanned and lethargic from months of active treatment would fail to respond in the natural way to a traumatic irritation of this severity by the extrusion of a few pus cells The following case shows the futility of indiscriminate massage

A patient seen recently was having regular massage for old-standing prostatitis. He consulted me on account of painful micturition and slight hæmaturia which accompanied the treatment I found the urinary passages normal, except for calculi in the prostatic gland !

A second case is eloquent of over treatment

A patient with a first attack of gonorrhœa consulted me two months after the onset Bladder irrigation had been attempted unsuccessfully twice a day from the start until a left epididymo-orchitis was achieved three and a half weeks later After an interval of a fortnight bladder irrigation was again instituted and combined with prostatic and anterior massage on a sound every day In addition, four injections (? vaccines) were given each week After a month of this treatment a smear from the urethra still contained gonococci—and no wonder !

In other coccal invasions we tend more and more to discount energetic local measures and try instead to build up the patient's resistance Occasionally we effect a cure by extirpating a focus, as in early appendicitis but otherwise we help the patient to recover The gonorrhœal patient demands cure more urgently than most and we seem to have taught him to believe that this can only be achieved by assiduous and unpleasant manœuvres. Is the gonococcus an organism with unique behaviour or is its treatment determined by fear and ignorance on the one part, and lucrative credulity on the other ? Present methods unfortunately not only lack the corrective of general hospital practice but indeed are encouraged by a municipality which allots its monetary grants to the various units in proportion not to the number of patients treated but to the total number of individual attendances in each department in the course of a year

Surely a premium on over treatment !

I am Sir yours faithfully

A CIVILIAN AMBULANCE SERVICE

To the Editor of THE LANCET

SIR,—While the Home Office and local authorities debate and mature their plans for the protection of the civilian population in the event of war and aerial attack while doctors and policemen are given instruction in anti gas measures and moneys are voted for the expansion of fire brigades we seem to hear comparatively little discussion of arrangements for the collection sorting evacuation and treatment of the numerous civilian casualties which must we know be visualised as occurring in spite of all these measures

The lessons of the last war and of Madrid with their small scale raids have at least given us some measure of what we may some day have to anticipate and we have reason to believe that gas and incendiary bombs may now be added to high explosive One or two large scale raids might easily fill all the hospitals of a city to overflowing City hospitals themselves might not escape damage It is evident that, in addition to aid posts and clearing stations, large fleets of ambulances would be needed and that a circle of schools and other suitable buildings well beyond the outskirts of exposed towns would have to be equipped as hospitals to receive the casualties

There are many medical men in this country who will be unwilling, for conscientious reasons, to serve with the armed forces in any future war There are also thousands of men of military age who will refuse to fight or make munitions Remembering the fine service given by the Friends' Ambulance Unit and the British Red Cross Society during the last war on behalf of sick and injured civilians, should we not be turning our thoughts to the provision of an adequate medical service for our own civilian population in the event of the attack which we hope will never come? Such a service would incidentally provide urgent and essential humanitarian tasks for numerous volunteers who might be unable or unwilling to serve with the armed forces in any way For London alone an efficient organisation would require an army of able bodied ambulance drivers, stretcher bearers, and orderlies

There would be no lack of doctors and nurses with experience, both clinical and administrative, gained in the last war, and it should be possible for these, in coöperation with the Quakers, the Red Cross, and St John Ambulance, and with or without the help of the Government or the municipalities, to organise an efficient scheme Such a scheme would be in the national interest At the same time it is not inconsistent with pacific endeavour to envisage alternative forms of humane assistance in the event of war While making provision for stricken men, women, and children, such an organisation would help to disarm bitterness and avert a vast amount of unhappiness in connexion with conscientious refusal to give military service

I am, Sir, yours faithfully,

Cambridge March 11th JOHN A RYLE

MORE AND SAFER MILK

To the Editor of THE LANCET

SIR,—In a recent issue (Feb 13th) Dr Esther Carling quoted the words of the Minister of Health "The more the consumption of milk is increased the more important does it become to secure the safety of the supply," and went on to suggest that it is the business of the medical practitioner to coöperate with the health authorities to ensure the prevention of milk borne disease Although agreeing with Dr Carling's suggestion, I doubt if many practitioners know how the milk trade is carried on in a rural area or if they realise the many difficulties met with in the production of a first-class supply Let me describe the methods of production and supply in the small area of the agricultural county in which I practise

A Milk Distributing Depôt—There has recently been established in the neighbouring small industrial town a milk depôt, to which milk is brought by lorries in churns from many of the surrounding farms A sample of the milk is tested and the remainder is strained, pasteurised, and dispatched to London in clean churns Some of the milk is kept to separate into cream and for the making of butter Broadly speaking none of the milk, cream or butter is consumed locally This depôt is well organised

A Large Scale Farmer—A farmer who has several hundred head of cattle deals directly with London through his bailiff, in his case the milk is only chilled From time to time his herd of cattle is inspected for tuberculosis. The standard of efficient organisation there is poor In a similar fashion another farmer collects and distributes his milk to the city of Oxford

A Small Scale Farmer—An extremely industrious and hard working couple have about fifty head of tuberculin tested cattle, with the help of one assistant they run the farm and distribute the milk themselves The milk is chilled and delivered by a small motor van, twice daily to the inhabitants of the small local town This small concern is exceedingly well run, and it seems a pity that most of the profits are swallowed up in bad debts

A Milk Collector and Purveyor—Two men collect all the milk produced by a local farmer from a herd of tuberculin tested cattle The milk is chilled and is taken out on a morning and evening round in churns by a horse-drawn milk float These men are tireless workers, spending their entire lives collecting and distributing milk locally In spite of their labours they find it difficult to make a living owing to the usual bad debts and the comparatively small amount of milk consumed by the average rural and small town householder

Milk Shop Purveyors—There is a shop in the small town to which all milk is brought in churns by rail from the nearest large town and is bottled on the premises A second purveyor has all his milk brought from London by rail daily, he is one of the few men who sells tuberculin tested milk

Other Sources—One or two queer old men drive about from village to village in decrepit horse drawn carts On the tail board reposes a remarkably battered looking churn filled with milk from local farms This they retail in surrounding villages

There are some interesting points about these arrangements It is, for instance surprising that a large number of consumers in the country obtain their milk from London or from one of the large towns, even when the source of supply is almost at their door The milk thus obtained is usually better prepared but must lack something in freshness, as is proved by the frequency with which it goes sour in summer It is also surprising that the consumption per head of the population is so small, a delivery of one to one and a half pints being the usual daily order for a family of two adults and three children (not infants) Free milk is distributed at the senior school in the town but not at the junior school Some of the village schools also provide free milk, although the mothers often object as they consider it "takes the child off his food at dinner time"

On questioning the producer farmers about the Milk Marketing Board and its effect on their trade one generally hears the black side of the financial position and one cannot but realise that milk is produced at about the lowest possible figure consistent with making a reasonable living The collector and the purveyor tell the same story, and no one who has had the opportunity of studying them at close quarters can fail to recognise how extremely hard they have to work A seven day week is inevitable with no holidays, not even Christmas day off My own experience shows that their health suffers as the result of this perpetual strain

Before one can fairly talk about "more and safer milk," or insist that the further improvement in the milk supply is the duty of medical practitioners, we must take an unbiased view of the difficulties of the field worker striving to make a living out of the milk trade Personally I fail to see how we can expect further improvement without readjustment in the financial balance between producer, retailer, and customer Exactly how this can take place is the real problem Can it be effected by or through the Milk Marketing Board or must the consumer pay for and probably consume less of a safer cleaner milk ?

The present-day farmer or retailer as I know him is a knowledgeable man and is fully aware of the need for cleaner milk and of the methods for obtaining it but he simply cannot bear the expense of these methods unless he is a philanthropist or is prepared to go into the bankruptcy court

I am Sir yours faithfully

March 15th LIEUT -COL. I M S (retd)

INFLUENCE OF SCHOOL ROUTINE ON GROWTH AND HEALTH

To the Editor of THE LANCET

SIR,—The interesting article by Mr John Allan in your last issue bears out the conclusions reached from a research carried out by the National Council for Mental Hygiène in 1931 which were embodied in a pamphlet entitled School Life and Nervous Instability published by the council

Thirty nine schools of every type covering the ages from 5 to 18 and with a total population of 10 125 children were approached with a view to finding out the effects of the conditions of school life on the physical and mental health and development It was found that the maximum period of strain occurred during adolescence and that retardation in growth as evidenced by height and weight tended to occur during the summer term especially when examinations and school sports added to the child s burden This period also appeared to coincide with an increase in punishments, which may also be regarded as evidence of an increase of emotional instability in the children and possibly in the teachers The returns appear to show two periods of maximum instability one occurring at puberty and one between 16 and 17

Evidently a careful recording of height and weight is extremely important and we agree with Mr Allan that it is a matter for regret that the Board of Education medical authorities are basing their estimates of nutritional states on clinical observations only without regard to the standards of height and weight for age

The whole question of the school curriculum as regards both work and play in relation to the growing child requires much more attention than it has hitherto received since damage done during the years of growth and especially between the years of 12 and 18 can never be retrieved

We are Sir yours faithfully

NITROUS OXIDE ANALGESIA IN OBSTETRICS

To the Editor of THE LANCET

SIR —I read the paper in your last issue by Dr Chassar Moir with much interest For some years before gas and air machines were introduced I made use of pure nitrous oxide gas during labour with satisfactory results and in a letter to your columns (*Lancet* 1931 2 427) I described a simple light, portable apparatus with reducing valve automatic filling valves for the bag and a self administering stop cock Dr Ivan Magill and Messrs Charles King Co Ltd had helped me to construct it

The apparatus described by Dr Chassar Moir is an improvement on this as it could be entrusted to midwives A self-administering stop-cock was awkward The new face-piece with expiratory valve is much more convenient for patients

I am Sir yours faithfully

Plymouth March 14th JAMES RIDDELL.

FACING THE DIPHTHERIA PROBLEM

To the Editor of THE LANCET

SIR —In the reference to the initiation of diphtheria immunisation at Markfield in your last issue (p 664) there is one slight inaccuracy It is stated that I and the doctors associated with me considered 50 per cent. of consents would be sufficiently high to prevent epidemic prevalence. What I actually stated was that anything under 50 per cent would probably render the procedure not worth attempting This of course is a very different thing

You will, I am sure be glad to know that we have succeeded in immunising about 90 per cent of the children and to have accomplished this in a large industrial village in Leicestershire the Mecca of the antivaccinationists is I submit a remarkable achievement

I am Sir yours faithfully

T W GORDON KELLY
March 1 th M.O H Market Bosworth Rural District.

ANOREXIA NERVOSA

To the Editor of THE LANCET

SIR —Dr Sheldon s article in your issue of Feb 13th and the comment by Sir Walter Langdon Brown Dr William Sargant and Dr W S Maclay are of extreme interest and show a serious effort by the medical profession to remove further the stigma of neurosis from patients presenting evidence of a major metabolic breakdown That such metabolic disorders can be of endocrine origin because of a metabolic control possessed by the anterior pituitary gland has been indicated by Dr Sheldon Recent experiences with two fatal cases both of which presented the clinical features of anorexia nervosa clearly indicate the seriousness with which some of these cases must be viewed.

Both cases suddenly developed coma which lasted about 30 hours in spite of hypoglycæmia therapy and was terminal In both cases the level of blood-sugar in coma was 20 mg per 100 c cm of blood Administration of intravenous glucose and adrenaline failed to rouse these patients beyond a semi-stuporous state and the maximal rise of blood-sugar under therapy was below 60 mg per 100 c cm of blood The post mortem in the female aged 24 diagnosed Simmonds s disease (anorexia nervosa however had been the diagnosis for the past five years) showed atrophy of the pituitary and an enlarged pancreas Prof Rasmussen studied the pituitary gland and reported atrophy in size and weight to 50 per cent of normal and microscopically extensive atrophy and degeneration of the anterior lobe

The second case a female aged 56 was admitted in coma and presented the typical appearance of anorexia nervosa The post mortem revealed a normal pituitary gland macroscopically and on cross section a normal size pancreas and extensive macroscopic hæmorrhage in both adrenal glands The microscopic study of the adrenal showed practical destruction of all cortex tissue by hæmorrhage The pituitary gland was not studied microscopically because it was mislaid by an attendant

The sudden terminal events in two out of my seven cases presenting the clinical type Simmonds s disease or anorexia nervosa syndrome indicate to me that one must be very careful to understand the vague symptoms of hypoglycæmia for they can be assigned to a neurotic background. Later investigation of my two fatal cases established the fact that both individuals had experienced the neurotic and psychic symptomatology of hypoglycæmia for five years preceding the fatal attack Sir Walter Langdon Brown has indicated the vagaries of blood sugar studies We have much to learn concerning blood sugar in the human, as indicated by Goldzieher (*Endocrinology*, 1936, 20, 86) demonstrating six types of sugar tolerance curves in endocrine cases with a hypoglycæmic syndrome

A small series of patients administered Collip's adrenotropic factor indicate the possible rôle of this substance in blood sugar control One patient has had a plateau type of sugar-tolerance curve, determinations made six months apart, with corresponding symptomatology Following the administration of 1 c cm of Adrenotropic Hormone (Collip) three times a week, a pre diabetic sugar curve and glycosuria (first- and third hour specimens) appeared

I share the hope with other of your correspondents that critical studies, as suggested by Dr Sheldon, of these cases will be made before the "neuro" tag is wired on a possible medical casualty

I am, Sir, yours faithfully,
CHARLES W DUNN
Philadelphia, March 3rd

ON THE TAKING OF CHILDREN'S TEMPERATURES

To the Editor of THE LANCET

SIR,—*There are three ways of taking the temperature* in the mouth, in the rectum, and in the axilla or groin Each method has its own special advantages and advocates Personally, I suggest that taking the temperature in the groin or axilla is the soundest and safest method

The advantage of the rectal method is that in tiny infants it is quick and easy There is no danger of breaking the thermometer The disadvantage is that it is one degree higher than the normal, and once the nurse or mother has seen the thermometer register at 99 4°, no amount of argument can make her feel that the temperature really is normal. She has a subconscious feeling that the child must be ill. Another very real disadvantage is that when a tiny infant's temperature is taken rectally several times daily, the thermometer acts as a stimulus to the anus, just as a soap stick or tip of the little finger would in a constipated infant, so that after the removal of the thermometer the infant tends to pass a motion, and diarrhœa can actually be provoked in an infant by frequently taking the rectal temperature Last, and not least, infections may be transferred from one child to another, or from outside sources, into the anus, and strong antiseptic solutions, unless carefully wiped off, may actually do considerable damage Everything taken into consideration, the habit of taking the temperature of infants and young children rectally is to be deprecated

Taking the temperature by mouth is impossible in the tiny infant with any degree of safety, but in the older child it has the advantage of being quick and accurate On the other hand, the danger of the child biting the thermometer is a very real one There is also a very real risk of transferring infection from child to child, or from adult to child, depending on who last used the thermometer, antiseptics may not be efficient in sterilising the thermometer after use Taking children's temperatures by mouth is not in my opinion, to be recommended

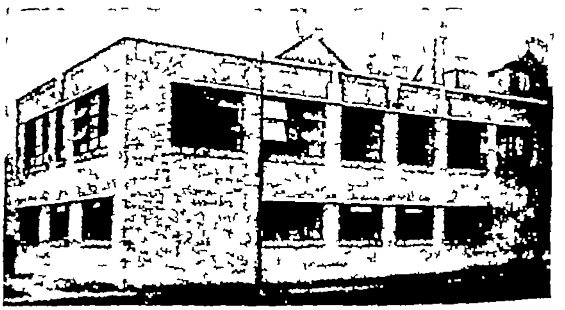
The axillary or groin temperature is the method of choice, although it takes longer The thermometer should be left in place for five full minutes, and tends, when the child is healthy, to be perhaps half a degree too low When a child is ill for any reason, the skin temperature as a rule approximates to the mouth and rectal temperature to within two tenths of a degree This is a negligible error No infection can be conveyed in this fashion The infant can be held on the mother's or nurse's knee, with the thermometer tucked into the groin or under the arm, and it can be nursed until the thermometer is read In older children who are lying in bed it is easily placed in position The risk of breaking the thermometer, in my experience, is very small, and altogether this method is preferable Psychologically, the effect of taking the skin temperature, rather than the mouth or rectal temperature, and finding it on the low rather than the high side in health, is of great advantage, and the over anxious mother or nurse can feel quite happy and sure that the child has no fever

I am, Sir, yours faithfully,
DONALD PATERSON
Devonshire place, W , March 16th

MARIE CURIE HOSPITAL

HELEN CHAMBERS RESEARCH LABORATORIES

THE new building which Queen Mary is opening to day, Friday, at the Marie Curie Hospital is situated between the two existing blocks of the hospital to which it has direct access by means of covered ways The laboratories which occupy its upper storey have been planned to afford facilities for carrying out the routine pathology of the hospital as well as for the development of work in cancer research, with particular regard to the experimental approach One laboratory is equipped for routine clinical pathology and histology Separate rooms are provided for bacteriology and for biochemistry Two rooms are equipped to house animals for work in experimental pathology and the pathologist's private room is also fitted as a research laboratory A sterilisation room and a room for the preparation of media and a mess room for the technical assistants complete the unit, which is in charge of Dr Mary Gilmour under the general direction of Dr Elizabeth Hurdon



KEIGHLEY VICTORIA HOSPITAL —It is proposed to build a new operating unit, with two theatres, and a block of five children s wards at the south west corner of this hospital It is estimated the extension will cost about £15,000

OBITUARY

FREDERICK WILLIAM ALEXANDER O B.E M.R C.S Eng , L.R C.P L.M Edin D.P.H

Dr Frederick Alexander who died on March 14th at his home in Teddington was widely known for sanitary labours and his keen interest in many questions of public health. He entered St Bartholomew's Hospital as a medical student in 1877 and qualified as M.R C S Eng in 1881 taking the Edinburgh diplomas later After qualification he served for a term as a surgeon on H.M S *Dunkeld*; later he was assistant medical officer at the Mile End road Infirmary and was then appointed medical officer of health to the borough of Poplar a post which he filled with conspicuous success for 34 years gaining well deserved popularity for his close attention to public welfare A careful executive officer he made special reports on the prevalence in his dispensation of infectious diseases and made close inquiry into the quality and value of different foodstuffs and into the purity of many substances in common use, cosmetics, and tobacco He wrote on these subjects forcibly He came into prominent notice by his insistence upon the danger consequent on the uncleanliness of the water in public baths He instituted at Poplar an electrolytic disinfectant plant for the purification of the swimming bath water an innovation which subjected him to considerable criticism. But there is no doubt that he was a pioneer in the movement which led to the interference of the Ministry of Health and the laying down of regulations for ensuring that the water in public baths should be kept pure in accordance with scientific direction His interest in the baths led him to the invention of an ingenious device for teaching the young to swim The occurrence of an epidemic of small pox during his term of office led to particular attention to the prevention of blindness among the infant patients, while special reports issued by him on the relationship of vitamins to foodstuffs and on artificial light treatment showed his resolution to keep abreast of modern therapeutics On his retirement from office he received the O B F

About ten years ago he went to live at Teddington, where he continued to manifest his wide interest in practical hygiene while he made a special study of the needs of the blind devoting to the subject much time and attention He made useful innovations in the methods of instruction in Braille characters which enabled the sighted instructor to more readily instruct the students, and he constructed models for teaching the blind the elements of electricity and magnetism He was a skilled mechanician and he adapted a large number of games and puzzles in such a way that they became practical recreations for the blind; models of these were reproduced in large numbers through the voluntary coöperation of amateur woodworkers and the results were distributed free of charge

Dr Alexander was a very able and energetic man. His inspiration throughout a full and active life was always the same—to be of service to his fellows He had reached his 78th birthday a few weeks before his death

EDWIN JAMES WENYON M.B B.Sc Lond

Dr Edwin Wenyon who died on Feb 20th after little more than a day s illness at the age of 84 had practised in Dundee for 30 years As a student first in Edinburgh then in London he had a brilliant career His London B.A was followed by the B Sc. degree with honours in experimental physics He won the science entrance scholarship to Guy s Hospital and the Sands Cox exhibition in physiology In the second M.B examination he was awarded the gold medal in anatomy and honours in physiology After serving as house surgeon at Guy's and some experience at the Rotunda, Dublin he went as officer of health to the Orkneys, For a brief term only he said but the wild islands of the North laid their spell on him and many years passed before he came away He then spent a short time in his native county of Staffordshire and settled finally in Dundee His interests were many and diverse A wide reader in his own language in French and German he was a capable and vivid critic of men and events the world over In his earlier days farming and agricultural chemistry attracted him he found time to grow melons and black oats and carnations He was the first in the Orkney Islands to succeed in growing strawberries in the open air At one time he had a fernery in which was a specimen of every British fern. Riding was for many years a favourite exercise; he broke in himself several horses for his own use He was also a great walker and keen fisherman. A true lover of Nature the familiar open two-seater in which he made his rounds was a proof of his inveterate love of the open air In his prime he could defy any challenger at chess

No hobby or sport however roused in him such absorbing interest as did children—well or ill. He waged constant war on errors of diet whether the result of ignorance carelessness, or poverty Associated with a wide experience and clinical skill were other qualities which gave to this man of undoubted genius a remarkable and lovable personality His unfailing kindliness his cheerfulness and gaiety of mien radiated hope and courage As one of his friends has said To a multitude of young and old he was more than their doctor he was their understanding friend His quick yet kindly wit made him in any company a dominant personality He revelled in a grand argument, and with his elder brother the late Dr Charles Wenyon had many an intellectual battle A tale is told of Edwin Wenyon in the heat of argument tearing off his coat and shouting to his brother keep cool In his long life he had his full share of trouble but with an incorrigible optimism he refused to worry, and at 84 retained the unlined countenance of a much younger man while his eyes never lost their whimsical suggestion of the fun there might be in living.

He leaves a widow and of his thirteen children ten three sons and seven daughters survive him The eldest son is head chemist with Imperial Chemical Industries Ltd Huddersfield Another son Dr Edwin J Meredith Wenyon has been with his father in Dundee for six years and will carry on the practice

JOHN LIDDELL M D Edin

Dr John Liddell who died on Feb 28th after a brief illness while on holiday in Portugal was for many years a well known figure in the medical circles of Harrogate Qualifying M.B C.M. at Edinburgh in 1882 he had already tasted of scientific exploration in the pathological laboratory during the progress of research there for the causative organism of tuberculosis Koch however was first After practising in Winchester for some years he moved to Harrogate in 1891 having obtained M.D Edin

(Hons) in the previous year A monograph on the waters of Harrogate appeared from his pen in 1893, and his publications thereafter showed that his interests were in dermatological and rheumatic conditions He became hon physician to the Royal Bath Hospital at an epoch when pathological laboratories were unheard of luxuries, and the physician had to struggle to obtain a tiny pantry, furnished with his own microscope In result, most of the section cutting was done at home He was also hon physician to the convalescent home of the Sunderland infirmary In the new century he began to be interested in colonic lavage, and was instrumental in getting the corporation baths fitted with appropriate appliances, thereby earning the gratitude of many sufferers He remained to the end a firm believer in the Harrogate treatment and was a striking exemplar of its benefits

Dr Liddell was a member of the Harrogate Golf Club from its inception, having been a pioneer of golf in England in the days when players were glad to have for a course a field or two with a few holes dotted about to suit the convenience of the farmer Curling, too, when winters were winters, was a pastime which he introduced to Harrogate clubs Retiring some seven years ago, he eventually settled in Wiltshire only last summer He leaves a widow and a younger son, who is lecturer in physiology at Oxford and a fellow of Trinity College His elder son, a lieutenant in the 60th Rifles, died of wounds in 1916

ARCHIBALD FAIRLIE, M D Glasg

The death occurred at the end of February of Dr Archibald Fairlie after a brief illness He received his medical education at the University of Glasgow, where he graduated as M B , C M in 1889, proceeding in the following year to the doctorate He held resident appointments at the Western Infirmary, Glasgow, and at the Maternity Hospital, Glasgow, and practised for a time at Bebside, his connexion spreading to Blyth He was a promoter of all benevolent and charitable work in the Blyth area, was a prominent member of the British Medical Association, and worked hard in connexion with the St John Ambulance Association The public value of his services was recognised by his being appointed a J P for the county of Northumberland Dr Fairlie was an excellent clinical physician taking all pains to keep up with modern work, while apart from his professional interest he was a well known authority on the history of his neighbourhood His death at the age of 72 is a loss to all classes He was a widower and leaves two sons, both of whom are in the medical profession

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED MARCH 6TH, 1937

Notifications —The following cases of infectious disease were notified during the week Small-pox, 0 , scarlet fever, 1652 , diphtheria, 1087 , enteric fever, 41 , pneumonia (primary or influenzal), 1256 , puerperal fever, 38 , puerperal pyrexia, 122 , cerebro-spinal fever, 25 , acute poliomyelitis, 2 , acute polio-encephalitis, 1 , encephalitis lethargica, 1 , dysentery, 15 , ophthalmia neonatorum, 85 No case of cholera, plague, or typhus fever was notified during the week

Notifications of acute pneumonia were still much below expectation in London 56 per cent below in the country as a whole 26 per cent below

The number of cases in the Infectious Hospitals of the London County Council on March 12th was 3307 which included Scarlet fever 875 diphtheria 1048 , measles 25 whooping cough 592 puerperal fever 19 mothers (plus 11 babies) encephalitis lethargica 282 poliomyelitis 2 At St Margaret s Hospital there were 17 babies (plus 6 mothers) with ophthalmia neonatorum

Deaths —In 122 great towns, including London there was no death from small-pox or from enteric fever, 10 (0) from measles, 4 (2) from scarlet fever 21 (8) from whooping-cough, 35 (8) from diphtheria 58 (20) from diarrhœa and enteritis under two years and 181 (30) from influenza The figures in parentheses are those for London itself

Of the 145 deaths from influenza in the 122 great towns o England and Wales outside Greater London the largest total were reported from Birmingham 13 Liverpool 9, Manchester and Sunderland each 8 Newcastle upon Tyne 7 Gateshead 6 and Norwich 5

Hull reported 3 deaths from measles Stoke-on Trent Fatal cases of whooping cough were scattered over 14 great towns Liverpool reported 3 Fatal diphtheria was reported from 25 great towns 4 from Gateshead, 3 from Birmingham

The number of stillbirths notified during the week was 281 (corresponding to a rate of 41 per 1000 total births), including 42 in London

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

In the Abstract of Navy Estimates for 1937 the Medical Establishments and Services are estimated at £482,160 gross and £411,400 net For 1936 the estimates were £467,330 gross and £397,300 net

ROYAL NAVAL VOLUNTEER RESERVE

Proby Surg Lt R A Mogg to be Surg Lt

In the Abstract of Army Estimates, 1937, the Medical Services are estimated as follows gross, £1,107,000 , net, £1,055 000

ROYAL ARMY MEDICAL CORPS

Officers who wear spectacles when on duty, states a new Air Ministry Order, are responsible for providing themselves with a pair having the approved type of flattened side pieces which do not interfere with the wearing of a respirator Such frames can be readily obtained from optical firms

In the Abstract of Air Estimates, 1937, the Medical Services are estimated as follows gross, £466,000 ; net, £430,000 The figures for the year 1936 were gross, £405,000 , net, £382,000

INDIAN MEDICAL SERVICE

The following officers have assumed appointments in India Col J O Andrews, D S O , Deputy Director of Medical Services, Northern Command (confirmed from officiating appointment) , Lt Col G Wilson, O B.E M.C , D A.D M S (Mobilisation), Northern Command (confirmed from officiating) and Maj R Murphy, D A.D.M S , Waziristan District

Lt Col J G Gill, D S O , O B E , M C , Asst Director of Hygiene and Pathology at Army Headquarters, will be on leave in China and Japan from March 15th until the middle of May

The undermentioned officers have vacated appts in India —

D A.D M S —Lt Col P S Tomlinson, D S O , R A M C

D A D H —Maj J D'A Champney R A M C

D A.D P —Maj F J Hallinan, R A.M C

The undermentioned appts have been made in India —

D A D M S —Maj R Murphy, R.A.M C

D A.D H —Maj F Harris, M C , R A M C

D A D P —Lt Col A C Craighead, I.M S

Indian Medical Department —Asst Surg (1st Cl) F G Whitbread to be Lt (Sen Asst Surg) Maj (Sen Asst Surg) W G H Warner and Lt (Sen Asst Surg) S C Gomez retire

COLONIAL MEDICAL SERVICE

Dr W A. C Hortor has been appointed Medical Officer, Cayman Islands and Dr J I Rorrie Medical Officer, Jamaica Dr J Portelly and Dr W Young become Medical Officers, Superscale Grade A, Malayan Medical Service, Dr J H Bowyer and Dr J C Carson become Medical Officers, Superscale Grade B, Malayan Medical Service , Dr J A V Duncan becomes Assistant Director of Medical Service Nigeria , Dr L W Fitzmaurice Medical Officer and Bacteriologist, Bahamas , and Dr F W Vint, Senior Pathologist, Kenya

PARLIAMENTARY INTELLIGENCE

NEW ARMY REFORMS

In committee of supply on the Army Estimates on March 16th Mr Duff Cooper Secretary of State for War said that recruiting for the Territorial Army had increased steadily throughout the year In spite of the numbers who had necessarily left during the year the force to-day was stronger by 861 officers and 15,205 other ranks than it was a year ago Unfortunately, while recruiting had improved establishments had had to be increased as a result of the creation during the year of the 2nd Anti Aircraft Division and of the expansion of the 1st Aircraft Division The completion of these divisions and the provision of anti-aircraft defence for certain ports would add further to the establishments The total increase amounted to over 20 000 men as compared with last year and therefore though the strength had been increased by over 10 000 the Territorial Army was nevertheless further off from getting up to establishment than it was a year ago But they need not be discouraged by these figures So far as the Territorial Army was concerned they were undoubtedly in a rising market Great numbers of young men of the very best type were coming forward to join the anti-aircraft divisions

It had been decided to restore to the Territorial Army Associations the 2½ per cent cut on all grants which was introduced as an economy measure in 1928 This year a considerable increase in the training grant was to be made The cadet movement would no longer be dependent on private charity, and similar financial assistance would be given to it in future as it enjoyed in the past before recognition was withdrawn Recruiting for the Regular Army during the year had been worse than in the previous one It was of urgent importance that there should be a very substantial improvement for otherwise the Army would no longer be able to carry out its normal duties of furnishing garrisons required for maintaining peace and order throughout the British Empire

A number of reforms would be introduced in the ordinary curriculum of army life which Mr Duff Cooper hoped would increase the popularity of the Service The soldier s ration was to be increased to allow of four meals a day instead of three as hitherto At home stations an ounce of butter would be substituted for an ounce of margarine and the butter would be supplemented by half an ounce of margarine The daily ration of enlisted boys would be increased by an issue of milk or in other suitable ways. It had also been arranged that men living in married quarters or unable for other reasons to feed in mess should receive a sufficient allowance of food or money to ensure that they would enjoy the same scale of nourishment as that of their fellow soldiers Every effort was being made to improve the conditions of accommodation New barracks would include sleeping dining and ablution facilities Sitting rooms would be provided; hot and cold water laid on to every floor central heating throughout and arrangements were being made for increases in fuel scales So far as possible similar amenities were being extended to existing barracks, and married quarters were being brought up to the best housing standards of the day

NOTES ON CURRENT TOPICS

Factories Bill in Committee

The Factories Bill was further considered by a standing committee of the House of Commons on March 9th and 11th

Clause 6 (which provides for the drainage of floors in workshops) and Clause 7 (which requires the provision of sanitary conveniences) with minor amendment were agreed to

DUAL CONTROL

On Clause 8 (which provides that certain health provisions of the Bill shall be enforced by district councils as respects any factory in which mechanical power is not used) Mr H Graham White said there was anxiety in the minds of some members with regard to the principle of dual control of factories. Where a district council might not have a sufficient staff for inspecting works there would be a different standard It would be better if the whole responsibility was in the hands of the Home Office inspectors —Mr R. J Davies said that under the present proposals it was possible for a small factory with a small staff using mechanical power to be under the inspection of a Home Office inspector whereas a much larger factory where no mechanical power was used would be under the control of the district council —Mr Mander said there were parts of the country where there might be large works and a local council who might find themselves in a difficult position if called upon to take action against their personal or business friends In cases of that kind it was only the Home Secretary who could act with the necessary strength —Sir J Haslam suggested that the difficulty concerning dual control was covered by Clause 9 —Mr L. Silkin Mr W A Burke, and Mr A. Hollins urged that the clause should be reconsidered —After further discussion Sir J Simon said he hoped that when the Bill became law there would be a substantial increase in the number of factory inspectors and he wanted to use the additional staff to the best purpose There were some kinds of work which a Home Office factory inspector could do best and which nobody else could do In one sense there was dual control as suggested but the local authority and the factory inspector did not exercise their control at the same place and time and in that sense there was no dual control. He would further consider the matter and see whether there was anything which could properly be done The committee should have regard to Clause 9 with its provision for action by an inspector in default of a local authority

On Clause 9 Mr Short moved an amendment to give power to an inspector where he was satisfied that no proceedings had been taken by a district council for punishing or remedying an act or default, to take proceedings and recover from the district council summarily as a civil debt all expenses incurred in successful legal proceedings and not recovered from any other person The principle applied not only to factory and workshop inspection but also to housing accommodation and to tenants who had not been able to obtain their rights owing to the vicious opposition of property owners and some ratepayers —Mr R S. Hudson Parliamentary Secretary, Ministry of Health opposed the amendment —Mr R J Davies said there were some local authorities who would not move and others who moved so slowly that there could easily be an epidemic among employees in the meantime —The amendment was negatived by 28 votes to 15

Clause 10 (which empowers the Home Secretary in certain circumstances to authorise an inspector to act in default of a district council) was agreed to

MEDICAL SUPERVISION

On Clause 11 (medical supervision) which provides that where it appears to the Home Secretary that illness has occurred in a factory which is believed to be due to a process or other conditions of work or that because of changes in a process there may be risk of injury to the health of persons employed or that young persons are employed in work which may cause such risk of injury he can make special regulations requiring reasonable arrangements for the medical supervision (not including medical treatment) of persons or any class of persons employed there—Mr ELLIS SMITH moved the deletion of the words "not including medical treatment" The Bill, he said, did not conform to modern standards with regard to silicosis, lead poisoning, dermatitis, and several other industrial diseases It was not the fault of the employees that they contracted those diseases —Sir J SIMON said that the clause was doing something entirely new in factory law It was a clause which they could take some pride in, but it was not altogether reasonable to ask that an employer should bear the cost of the medical treatment of an employee There was national health insurance and elaborate arrangements in the matter of medical treatment were made by trade unions He was, however, prepared to modify the clause —The amendment was withdrawn and the clause agreed to with substitution for the words "not including medical treatment" of the words "not including medical treatment other than first-aid treatment and medical treatment of a preventive character"

Clauses 12, 13, and 14, tightening up the provisions for safeguarding machinery by fencing, were agreed to

QUESTION TIME

THURSDAY, MARCH 11TH

Alcohol and Road Accidents

Mr RICHARD RUSSELL asked the Home Secretary whether, in view of the probable heavy increase of motor traffic during the period of the Coronation festivities, he would, by circular or otherwise, draw the attention of the magistrates to the great increase of road accidents at festive seasons, when, as last Christmas, added drinking facilities were permitted, and recommend the closest scrutiny of the claims for lengthened hours of drinking during the Coronation celebrations, especially at times when larger crowds at a later hour of the day made caution on the roads specially necessary —Sir JOHN SIMON replied I feel sure that magistrates will not fail to take into account all relevant points when considering applications for such extensions during the Coronation festivities The limited extensions which have been granted on similar occasions in the past are not, I am informed, shown to be the cause of increased accidents

Children Born in Prison

Mr ANDERSON asked the Home Secretary how many children were born in His Majesty's prisons, and how many, if any, expectant mothers were released for their children to be born outside, for the 12 months ended December, 1936 —Sir JOHN SIMON replied During 1936 the numbers were 16 and 10 respectively

Hospital Staffs and Anti-Gas Instruction

Mrs TATE asked the Home Secretary what arrangements, if any, were being made by his department to send instructors and apparatus to hospitals, in order that hospital staffs might become proficient in the use of gas masks and the necessary steps to take in the event of war —Mr GEOFFREY LLOYD, Under Secretary, Home Office, replied Sixteen medical instructors have been appointed who are giving instruction in anti gas precautions to medical practitioners, nurses, and medical students Up to the end of last month 3059 doctors, 2459 nurses, and 569 medical students had been trained Arrangements are made through the British Medical Association, the College of Nursing and the medical schools respectively, and the instruction is often given at a hospital

Mrs TATE In the event of a doctor in charge of a mental hospital who has taken steps to make himself efficient in the use of masks applying for permission to instruct a certain number of his staff, would that permission be given to him ?

Mr LLOYD It would be given in any event

Mr BELLENGER Is it the intention of the Government to centralise instruction mainly in the Home Office School ?

Mr LLOYD In regard to medical training these doctors are stationed at the various key points throughout the country

Mr CREECH JONES asked the Home Secretary what steps, if any, H M Government intended taking to see that the gas masks for sale in this country conformed to the Home Office specifications —Mr GEOFFREY LLOYD, Under-Secretary, Home Office, replied A procedure has been arranged under which private manufacturers may be licensed to affix a Home Office certification mark to respirators of their own or Government design, which comply with a Government performance specification. Under this procedure manufacturers are required to submit specimens for examination and a test of performance If the article is satisfactory a licence is granted to affix the Home Office certification mark This licence remains in force for six months and thereafter until brought to an end by the Government The process of manufacture, the components of respirators and completed respirators are subject to Government inspection

Women and Young Persons and the Two-Shift System

Mr HOLLINS asked the Home Secretary whether he would consider the publication at his earliest convenience of a list of firms, and their location, working the two shift system under the Employment of Women and Young Persons Act, 1936, showing, respectively, the two-shift orders which had not been used during a period of two years and thereby expired, the orders which had not been operative during a period of one year which might be revoked, and other orders remaining in force , and whether he would consider the publication of such a list at least once a year —Sir JOHN SIMON replied The factory inspectors have been instructed to collect information as regards existing orders for the first six months of this year When their reports are received, I will consider the points raised by the hon Member

Perishable Foods

Mr HERBERT WILLIAMS asked the Minister of Health what steps he was advising the local authorities to take to avoid food poisoning in those districts where the suitable or sufficient temperature of shops had been fixed so high that there was a danger of the bacteriological infection of perishable foodstuffs —Sir KINGSLEY WOOD replied In deciding what temperature is suitable and sufficient it is for the local authorities to have regard, inter alia to the nature of the goods sold in the shop, and I have no reason to suppose that they are not alive to the importance of this consideration

Approved Societies and Additional Benefits

Mr JAMES GRIFFITHS asked the Minister of Health the average cash value of the additional benefits provided by approved societies under the National Insurance Acts , and what was the highest and the lowest additional benefit so provided by approved societies —Sir KINGSLEY WOOD replied I assume that the hon Member refers to statutory rates of sickness, disablement, and maternity benefits The average increase, covering some 70 per cent of the insured population, is about three units, that is 3s a week in respect of sickness benefit, 1s 6d in respect of disablement benefit, and 6s in respect of maternity benefit Some approved societies have made no increase, while some of the most prosperous have made an increase of five units and also devoted funds to various treatment benefits

Private Nursing-homes in Marylebone

Mr LIDDALL asked the Minister of Health whether he was aware that the London County Council had recently, in collaboration with the Marylebone Council, reviewed and weeded out the private nursing homes converted from single or adjoining decayed dwelling houses in the back streets of Marylebone and if he would call for an report on the results —Sir KINGSLEY WOOD replied I have no official information on this subject, but I will communicate with the London County Council and inform my hon friend of the result

The Trend of Population

Mr CARTLAND asked the Minister of Health whether he had set up the committee to investigate the trend of population if so, what were its terms of reference who were its members , and whether it was open to receive evidence from outside sources —Sir KINGSLEY

WOOD replied: The Registrar-General is continuing and extending his investigations and researches into this matter Consultation is also proceeding so as to secure the coöperation of the committee recently formed under the chairmanship of Prof Carr-Saunders and I think at the present stage this is the most useful course to adopt I will from time to time inform the House of the progress made in this important matter

Telephone Facilities and Urgent Illness

Lieut -Colonel WICKHAM asked the Postmaster General whether he was aware of the difficulties experienced by inhabitants of small villages unprovided with telephone kiosks in cases of fire sudden illness, and other emergencies; and whether he could see his way to reduce the existing rental of £4 for five years or alternatively to spread the total amount over a longer period.—Sir W WOMERSLEY Assistant Postmaster General, replied I am aware of the difficulties but they differ in degree with local circumstances, and it is necessary to maintain some fixed standard of discrimination Under the Jubilee concession kiosks will be provided without special payment in every village or hamlet where there is a Post Office and facilities do not already exist It would not be possible to provide kiosks in every village or hamlet throughout the country without overloading the finances of the department and delaying other work. Under the tercentenary concession therefore any village or hamlet can have a kiosk if the local authority with its special knowledge regards the local need for a kiosk as sufficient to justify it in paying for a period limited to five years a rental of £4 equal to the minimum rental paid annually by a subscriber I regret that I cannot see my way to reduce the sum or to spread it over a longer period at any rate during the present heavy pressure of demand upon the department s resources

The Cost of Living

Mr SHINWELL asked the Minister of Labour the percentage increase in the cost of living between February 1935 and February 1936 —Mr ERNEST BROWN replied: According to the statistics compiled by my department relating to the cost of maintaining unchanged the pre war standard of living of working-class families the average level of the cost of living of such families was approximately 42 per cent above the pre-war level at 1st February 1935 and 47 per cent above the pre war level at 1st February 1936 These figures indicate an increase of approximately 3½ per cent in the cost of living between the two dates

Cremation

Mr THORNE asked the Home Secretary how many crematoriums there were in this country; and how many people were cremated in 1937 —Sir JOHN SIMON replied The number in England and Wales is 20 I have no information as to the number of persons cremated this year but the total number of cremations in England and Wales last year was 10 188

MONDAY MARCH 15TH

Health Insurance: Juveniles and Medical Fees

Mr RHYS DAVIES asked the Minister of Health when he intended to introduce a Bill to bring into health insurance young persons on entry into employment; whether he had now come to an agreement with the medical profession as to panel fees in respect of such persons and if so what was the amount agreed upon —Mr HUDSON Parliamentary Secretary to the Ministry of Health, replied: My right hon. friend cannot say at present when this Bill will be introduced The question of the doctors fees for the young persons referred to has become bound up with the larger question whether the fees now paid for all insured persons call for revision by way of increase or decrease and my right hon friend has agreed with the suggestion of the medical profession that the whole matter should be referred to an independent Court of Inquiry

Medical Practitioners and Health Insurance

Mr LYONS asked the Minister of Health if he would state for the years 1935 and 1936 respectively the number of medical practitioners undertaking national health insurance work in this country; and the total amounts paid for such services out of national health insurance funds —Sir KINGSLEY WOOD replied: The numbers of medical practitioners under agreement with insurance committees in England and Wales in 1935 and 1936 were 16 552 and 16 700 respectively and the total amounts paid to them from national health insurance funds in respect of those years were £7 345 338 and £7 728,000 The last-named figure is approximate as the returns of expenditure are not yet complete

Children and Inflammable Cinema Films

Mr SIMMONDS asked the Home Secretary what action he proposed to take to prevent the sale of inflammable cinematograph film to children —Sir JOHN SIMON replied: This is a difficult matter which has been receiving much consideration and I should be glad to discuss the question with my hon friend

Milk Adulteration

Mr DAVID ADAMS asked the Minister of Health whether he was aware that cases in recent prosecutions by the Newcastle Corporation, under the Food and Drugs (Adulteration) Act 1928, Section 16 (2) of vendors selling new milk deficient in non fatty solids 17 2 per cent and 15 4 per cent respectively were dismissed by the magistrates; and whether as deficiencies on this scale indicated the presence of added water he would consider legislation for the more adequate protection of the public in this matter —Mr HUDSON replied My right hon. friend was not previously aware of these cases, but he has now received a communication from the town clerk with regard to them My right hon. friend is making further inquiries and will communicate with the hon Member when these are completed

Diphtheria in Huddersfield

Mr GROVES asked the Minister of Health how many cases of diphtheria had been recorded in Huddersfield in children who had been immunised against that disease; and whether there had been any deaths in immunised children during the period in which immunisation had been practised.—Sir KINGSLEY WOOD replied I have been in communication with the local authority and the following is the information which they have furnished on this subject: Approximately 50 per cent of the children of Huddersfield have been immunised to protect them against diphtheria During the past four years amongst the 50 per cent not treated by immunisation there were 1138 cases of diphtheria resulting in 133 deaths During the same period amongst the 50 per cent treated by immunisation there were 40 cases of diphtheria resulting in one death. The one death referred to above is the only instance in which a death has occurred in a child who had been immunised

Cheap Milk for Mothers and Young Children

Mr DAVID ADAMS asked the Minister of Health whether it was intended to make the scheme for the provision of cheap milk for expectant and nursing mothers and children under school age general throughout the country; and whether its application for the six summer months only would be extended to the whole year in future —Mr HUDSON replied: It is the intention of the Milk Marketing Board and the Commissioner for the Special Areas that the schemes which have been in operation in Rhondda since July 17th 1936 and in Jarrow since Jan 1st 1937 should run until Sept 30th 1937 but before that date the Board and the Commissioner will consider the results with a view to a decision on the future of the schemes

TUESDAY MARCH 16TH

Public Kitchens in Necessitous Areas

Mr WILSON asked the Minister of Health whether in view of the popularity which had attended the establishment of milk bars he would consider the possibility of setting up in some of the more necessitous areas public kitchens where at a small cost the more nutritious kinds of food could be supplied either for consumption on the premises or otherwise —Mr HUDSON, Parliamentary Secretary to the Ministry of Health, replied I am afraid that the action proposed would not be within the powers of my department

Expenditure on Mental Deficiency

Mr WILSON asked the Minister of Health whether he was aware that the expenditure in respect of mental deficiency which had fallen upon the rates of county and county borough councils had risen from £694,390 in 1929–30 to £2,031,949 in 1932–33, and whether he could explain the causes for such an increase —Mr HUDSON replied The figures quoted by the hon Member do not represent the real position The expenditure by local authorities amounted in 1929–30 to £1,500,244 and in 1932–33 to £2,191,847 An Exchequer contribution to the cost was paid in both years, in the former as a direct grant of 50 per cent of expenditure, in the latter as part of the Block Grant The increase in total cost shown by the figures I have quoted is due to the fact that it is a growing service and more attention is now being paid by local authorities to the matter

MEDICAL NEWS

University of Oxford

Dr H M Sinclair, lecturer in physiology and biochemistry in University College, formerly senior demy of Magdalen and Radcliffe scholar in pharmacology, has been elected to a travelling fellowship on the foundation of Dr John Radcliffe

Applications are invited by the Nuffield Committee for the whole time post of assistant director of pathology to work at the Radcliffe Infirmary The stipend offered is £1000 a year, and the committee will propose to the University that the title of Nuffield reader in pathology be conferred upon the assistant director Further information about the post may be had from the secretary of faculties, University Registry, Oxford, to whom applications should also be sent before April 26th

Mr Humphrey Neame has been appointed examiner for the diploma in ophthalmology in place of Mr P G Doyne

Dr Paul Fildes has been appointed examiner in pathology for the degree of bachelor of medicine in place of the late Prof E H Kettle

University of Cambridge

On March 12th the following degrees were conferred —

M D—D W Smithers

M Chir—W H G Jessop

M B B Chir—*F G Hinks *F B Thomas, *B L Williams *Alfred Rothwell *D G Freshwater *W J Montague C S Humphries A D Ledward N D Jekyll V C Robinson E G K Williams, G I Watson I C Fletcher B C M Palmer E O Walker G L Broderick H D Johnson, G S W Organe, A M McFarlan R G M Keeling and F D M Livingstone

* By proxy

The title of the M B degree has been conferred on M Ball and of M D on A M Stewart

University of Manchester

Dr Stanley Hodgson has been appointed lecturer in forensic medicine and Dr E N Rowlands chief medical assistant in the department of clinical investigations and research

London County Council

On Tuesday Mr Somerville Hastings was reappointed chairman of the Hospitals and Medical Services Committee with Miss E Rickards as his deputy Dr C W Brook resumes the chair of the committee on Welfare of the Blind

Fellowship of Medicine and Post Graduate Medical Association

The following courses will be given during April ophthalmology at the Royal Eye Hospital (April 5th to 17th), plastic surgery (April 14th and 15th), neurology at the West End Hospital for Nervous Diseases (April 19th to 24th), Week-end courses will be held in diseases of the heart and lungs at Victoria Park Hospital (April 10th and 11th) in fevers at Park Hospital (April 17th and 18th) in infants diseases at the Infants Hospital (April 24th and 25th), and in cancer at the Royal Cancer Hospital (April 24th and 25th) On Saturday, April 3rd there will be a special demonstration on pulmonary tuberculosis (at Preston Hall) and on Tuesday, April 6th, there will be a demonstration on the fundus oculi at 8 30 P M Both are intended for M R C P candidates Detailed syllabuses of all courses can be obtained from the secretary of the Fellowship, 1, Wimpole street, W 1

Royal College of Surgeons of England

A meeting of the council of the college was held on March 11th with Sir Cuthbert Wallace, the president in the chair Mr R B Wade of Australia was admitted an honorary fellow of the college Mr D H Patey was elected an examiner in pathology under the Conjoint Examining Board

The following hospitals were recognised for the six months' surgical practice required of candidates for the final examination for the fellowship

Victoria Hospital Burnley (house surgeon to Unit I and II), Withington Hospital, Manchester (resident surgical officer senior assistant medical officer Grade 2 junior assistant medical officer Grade 3) Prince of Wales's Hospital Plymouth (resident surgical officer and three house surgeons) and at Devonport (*senior house surgeon for one year only*) King Edward VII Hospital Windsor (three house surgeons)

A diploma of fellowship was granted to M H B Robinson and a diploma of membership to D V Hague Licences in dental surgery were granted to the following candidates —

G M A Brown A J Clegg H A Dixey F B Gamblen Eileen F Gawn J L Harrington B J Harrison C W Lawrence Frank McCombie N A McCormick K J Millett, F A Moore W R G Morris Bankim Mukerjee B W P Roberts N L Rowe V S Sams Jacques Schermant E C Sharp H B Shay Melissa Sprowson, Kurt Strauss J E Tudor, W K Weighell W D Westoby David Wolfe and J D Wren

Diplomas in ophthalmic medicine and surgery were granted jointly with the Royal College of Physicians to the following candidates —

Aziz Ahmed Edward Bacon A K Banerjee F P C Claffy, F J Darbyshire B K Das Gupta G S Dhillon, M L A Dubash M A K Durrani R L C Fisher, S A Foad V V Gupte Helen M Herbert R F Jamieson Eileen M Kennedy H M Kera Ram Labhaya C R D Leeds B N Pershad J D Maude Kathleen A Pih S M Ruwala Brendan Sheehan E C Srinivasan Jean W Strand K J Talbot and B D Telang

Jewish Hospital Medical Society

The Anglo Palestinian Club will be at home to this society on Sunday, March 21st at 8 30 P M, at 43 Great Windmill street, Piccadilly, for an evening of *medicine magic, music and murder* Mr Arnold Sorsby will be in the chair

The Zunz Fund

The trustees of this fund, which was established in 1899 have offered to distribute its capital to 34 London hospitals in more or less the same proportions as the annual grants being hitherto made The only condition is that the wards named after Annie Zunz which were supported by the annual grants shall be maintained in perpetuity If the offer is accepted about £425 000 will be distributed

Microchemical Club

At the annual general meeting of this club on March 13th the following officers were elected hon treasurer, Mr L H N Cooper Ph D, hon secretary, Mr J R O'Brien hon librarian Miss Isobel Hadfield, members of committee Prof H V A Briscoe Mr J Matthew, and Mr S J Folley Ph D

London Hospital

The ordinary income of this hospital has slightly decreased but it is expected that there will be a surplus of income over expenditure of about £4000 for the institution has received legacies amounting to over £18,000 It is however difficult to find funds for necessary capital improvements

New Mental Hospital

On June 14th the Minister of Health will open a new mental hospital at Runwell Essex, which is the joint scheme of East Ham and Southend-on-Sea Its cost has exceeded £650 000 and it will house 1000 patients and is provided with all modern equipment including a theatre.

London Homoeopathic Hospital

At the annual general meeting a letter was read from the Keeper of the Privy Purse stating that the King had been pleased to grant his patronage to the hospital Lord Donoughmore said that the past year had been a satisfactory one since much work had been accomplished and the finances had not suffered

A New Hospital for South London

A site has been acquired opposite the park in Lambeth road for a new hospital to be erected by the Institute of Trained Nurses of Our Lady of Consolation. The present small hospital is in Barkham terrace for which site £10 000 has been paid The new building is to cost £100 000

Royal London Ophthalmic (Moorfields) Hospital

The annual dinner of this hospital took place on March 11th at the Langham Hotel Mr T Harrison Butler presiding In his response to the toast of The Medical School, Mr C B Goulden, the dean incorporated a report of the year s progress He said that the school was flourishing and that students had joined the hospital in larger numbers than previously there being 1?4 new students during 1936 The examination results had been satisfactory The Gifford Edmond prize had been awarded to Mr J Bruce Hamilton of Hobart Tasmania a old student and senior resident officer for his essay on the significance of heredity in ophthalmology Apart from continuous clinical instruction 693 hours of lectures had been given. Mr Fincham had delivered a series of lectures on modern ophthalmic instruments and Prof Dodson on allergy Six series of demonstrations had been given to students of the Postgraduate College at Hammersmith. There had been several changes in the staff during the year Sir Stewart Duke Elder had resigned from the hospital, and Sir John Parsons who had lectured on physiology since 1919 had also resigned his lectureship To replace these the school had secured the services of Dr R J Lythgoe reader in physiology of the special senses in the University of London Dr Russell Brain had retired and in his place Dr Denis Brinton had been elected to the staff. Mr Frank Law had joined the staff and undertook the classes in practical surgery Mr C D Shapland had been appointed curator and pathologist and Mr R C Davenport was the new sub-dean The school still felt the need of a proper professorial unit in which full time officers could give more attention to the teaching Under the present arrangement it was impossible to do more and recently the help of chief clinical assistants had been obtained to give tutorial classes and these had been much appreciated

Appointments

ANN L., M D Lond., D P M has been appointed Deputy Medical Superintendent of Park Prewett Mental Hospital Basingstoke

DUX R. W M R C S Eng., Resident Surgical Officer at the Manchester Hospital for Consumption and Diseases of the Throat and Nose

ROY, IAN M B., M R C P Lond Hon Assistant Physician to the Aberdeen Royal Infirmary

KENNEDY, H H L D S., Assistant Dental Surgeon and

WALKIN, D GRIFFITH L D S Chief Assistant to the Dental Department

CONVERSAZIONE AT THE UNIVERSITY OF LONDON

LAST Tuesday evening the chairman of convocation was at home to the graduates of the University and their friends Over a thousand persons took the opportunity to see Mr Holden s beautiful senate house block of which the reception hall, panelled with travertine is a remarkable example of warm academic hospitality The other university buildings including the library and great tower are still in their early stages but already London University has begun to feel like a home to its graduates—and even to its undergraduates The guests were entertained on Tuesday with music dance and drama of a high grade but the real attraction was the opportunity of which free use was made for graduates of all faculties to meet each other and the administrative staff of the University Refreshment was comfortably served in various parts of the house and especially at the long tables in the long low refectory on the third floor

Births, Marriages, and Deaths

BIRTHS

BOULDEN —On March 9th at Canterbury the wife of Dr Peter Boulden of a daughter

BROWNING —On March 10th to Dr and Mrs S Barratt Browning at Wellington House Handsworth Wood Birmingham—a daughter

DENNING —On March 10th at Hong Kong the wife of Captain G M Denning R A M C of a daughter

GRAHAM —On March 14th at St. John s Wood N W the wife of Dr Walter Graham, of a son

LOWE —On March 14th at Lacock Wilts, the wife of Dr J B Lowe of a son

MCLEOD —On March 9th at North Walsham Norfolk, the wife of Dr T H McLeod of a daughter

SMELLIE —On March 7th at Sherwood Woking the wife of Mr W B Smellie F R C S , of a daughter

MARRIAGES

BALL—PEARSON —On March 9th, at St Marylebone Parish Church Peter H Ball R.A M C , only son of Dr C Ball, of Hunstanton Norfolk to Mary le Goyt younger daughter of J R Pearson C I E late I C S of Jersey

DEATHS

ALEXANDER.—On March 14th at Bankside, Teddington Frederick William Alexander O B E M R C.S Eng D P H , aged 78

BLAIR.—On March 14th at Hillfield Underhill road Clendon Ernest Blair L R C P Edin

BUSWELL —On March 13th, at Prince of Wales terrace Kensington W , Colonel Herberd Richard Buswell C M G , R.A M C (retd) aged 72

GALT —On March 14th at Taswell road Southsea Hants Lieut. Col Robert Gale D.S O M B Glasg R A M C (retd)

SCOTT —On March 12th at Fair Lea West Cliff road Bournemouth Bernard Scott M R C.S Eng , aged 78

WENYON —At Skailbrae Dundee on Feb 20th 1937 Edwin James Wenyon M B M R C S , aged 84 years

N.B —A fee of 7s 6d is charged for the insertion of Notices of Births Marriages and Deaths

NOTES, COMMENTS, AND ABSTRACTS

SCIENTIFIC RESEARCH IN INDUSTRY

ONE of the most important developments in industrial research in the last five years has been the formation of well balanced teams of workers—including chemists physicists engineers and, where necessary, biologists—whose steady march has replaced the sporadic bursts of brilliant individualists The Coöperative Research Associations are the main outcome of this movement and an encouraging summary of their work has been published in the report for 1935–36 of the Department for Scientific and Industrial Research.[1]

Many of the activities of the department are more or less directly connected with public health There have been for example many advances in the campaign against noise Besides the investigation on the problems of sound proof buildings tests have been carried out at the National Physical Laboratory on the reduction of noise from aircraft engines large electrical transformers road drills and traffic. An investigation has also been begun on the production of static electricity in operating theatres of hospitals In dry countries the ignition of explosive anæsthetics by sparking is recognised as a serious risk and it was considered *important enough in this country* to be investigated; experiments are being made on hospital equipment with the help of the medical authorities At the request of the Home Office a preliminary examination has also been undertaken of the risk of ignition in dry-cleaning works where some of the liquids produce an ignitable vapour when mixed with air Methods for detecting in the atmosphere small quantities of poisonous gases commonly occurring in certain industrial processes have also been worked out.

Researches for the Dental Board on dental amalgams have been completed during the year The results have shown that the composition of the alloy used in making the amalgam must lie within very narrow limits if the dentist is to produce fillings that will continue to fill cavities without contraction The precautions to be observed by the dentist in preparing the amalgam have also been established The conditions for both the manufacture and use of materials for amalgam fillings have been determined as the result of an extended series of experiments in which the changes of volume at mouth temperatures have been measured sometimes over long periods. The report claims that the results of this work if generally applied should place this country ahead of the rest of the world in this particular aspect of dentistry

Interesting physical work has been carried out in connexion with radium beam therapy The strength of the radiations from a specially designed radium unit with which varying radium-skin distances can be obtained, have been measured in a phantom a celluloid vessel containing water and giving the same scattering and absorption effects as the human body Means have been developed for accurately measuring and controlling tissue-dosage during treatment Another investigation is in progress on the weak radiations that may reach distant parts of a patient's body during treatment These it is believed may be important in contributing to the constitutional effects of radium therapy

The Food Investigation Board has made several interesting observations At the Low Temperature Station Cambridge the effect of radiation from radioactive substances in destroying bacteria are being studied in connexion with the storage of meat Owing to their great penetrating power it is possible to study the effects of γ rays on bacteria grown in nutrient media and experiments on *Bacillus coli* have shown that the lethal action of the radiation proceeds independently of growth in the medium. Under certain conditions abnormally long forms of *B coli* are produced analysis of viable and total counts and of measurements indicate that the production of these is due to division being inhibited, while growth itself is unaffected. The flesh of eels has been found to be an unusually rich source of vitamin A which however is distributed unevenly throughout the body being largely concentrated in the tail. Methods of storing eggs in different concentrations of carbon dioxide are being tried out on a large scale, a high concentration of about 60 per cent was found to prevent attack by mould The manner in which the quality of pork and bacon is related to the diet of the pig is being studied. In the diet an ounce of cod liver oil a day may be good for the living pigs but it causes the fat to become rancid in curing even when administration was stopped some considerable time before killing Heavy exercise before slaughter makes the pig's tissues more alkaline, a fact that has been found to be important in dry salt curing for alkalinity inhibits the diffusion of salt and sugar and predisposes to infection by the anaerobes that produce bone-taint By methods shown to be successful on a large scale and already adopted by several factories pollution by milk washings can be decreased by about 98 per cent It has been found that the *losses of milk, cream,* whey &c *can be reduced by* nearly three million gallons a year This recovered milk is used for manufacturing purposes thus saving about £50 000 a year to the industry

The Boot and Shoe Research Association is making very careful records of the way in which various people walk by means of cinematograph records and by measuring with electrical thermometers the skin temperature of the feet when wearing different types of shoes Various gaits and the effect of different kinds of shoe upon them are also being investigated The results suggest that some shoes usually considered suitable are much more likely to interfere with the normal gait than others and this is throwing light upon the essentials of correct shoe design and construction

In spite of the many advances, the report however still regards the position of the research association movement as a whole as not yet entirely satisfactory The department is prepared to provide a further £60 000 each year to the support of these associations and would have found that sum in each of the past two years had industry been ready to make an equivalent contribution In fact the income of the associations might have been increased by a further £150 000 a year of which only half had to be found by industry if full advantage had been taken of the department's offers.

A QUESTION OF EMPHASIS

Dr G G SHERRIFF (Edinburgh) writes: The interesting article last week on medicine in Russia raises wider issues worthy of discussion The key section was the following: The primary concern of the medical service in the U.S.S.R is not with hospitals or with diseases and their cures but with the maintenance and improvement of the health of the community The care of the sick and their disposal to hospital becomes a subsidiary function In the public mind the emphasis has thus been shifted away from the idea of disease toward that of health which in itself helps to promote a healthy society —Although the more enlightened members of the profession in this country continually preach the need for the above change of emphasis, the *status quo* is little altered All the power and glory still belong to the experts in disease The higher degrees and diplomas so necessary for high preferment are based overwhelmingly on disease and the minute, even pedantic study of its protean forms Analysis flourishes, but synthesis languishes an exile from most curricula and syllabi those cast iron portals on the path of progress Until this radical defect is remedied the nineteenth century outlook will retain its predominant influence

H M Stationery Office 1937 Pp 195 3s

THE GREATEST EGYPTIAN MEDICAL DOCUMENT

HIPPOCRATES, whom we Europeans call the Father of Medicine, lived in the fifth century before Christ, and was according to Greek tradition born some nineteen generations after the deification of Æsculapius, that is about six hundred years after the profession had its origin The earliest Greek tradition, however, with which we are acquainted, that of Homer, did not recognise Æsculapius as a god, but simply claimed him as a "blameless healer" inspired by the God of Healing, Pæon But the Greeks themselves were a young people compared with the nations of the East, and in fact obtained a great, indeed probably a major, portion of their culture from the ancient Empires of the East And so Dr Ebbell dedicates his translation of a great Egyptian medical work[1] to the physician Imhotep, the acknowledged father of Egyptian medicine

The Papyrus Ebers can be dated with considerable accuracy to about the year 1550 B C, that is some 350 years before the siege of Troy, and at least 1000 years before the date of Hippocrates But even that was not the beginning There is extant another Egyptian papyrus which can be dated between three and four hundred years earlier, and the Papyrus Ebers itself contains references to written documents which were a thousand years old when it was compiled So the trail runs backward nor is it probable that the art of healing, which must have been one of the earliest professions to arise so soon as men had learnt to live with their fellows in communities, would not have been committed to writing directly written communication was invented As the corpus of knowledge and the numbers of aspirants increased some permanent record of medicinal lore became inevitable What was the ultimate source from which the Egyptians drew their knowledge of medicine is not and probably never will be known, but this much at least is certain, that the Papyrus Ebers represents the accumulated medical wisdom of many centuries

What then does orthodox medicine of 1550 years before Christ look like to us nowadays? Dr Ebbell has done his best for us with this translation and his learned and ingenious interpretations of what is only too often obscure In the course of years of study he has succeeded in finding probable interpretations for many of the words which were unknown to the Egyptologists of fifty years ago when the Papyrus first came to light Ebers bought it in Egypt in 1873 and printed it in full in 1875 But there still remains a large amount of words, expressions, references, and even whole sentences, the meaning of which is obscure Yet enough has been securely transferred to our modern tongue to enable us to assert the existence of a body of medical and surgical knowledge founded on careful observation One section reads thus "The beginning of the physician's secret knowledge of the heart's movement and knowledge of the heart There are vessels from it to every limb" "the heart speaks out of the vessels of every limb" The surgeon is told "If thou examinest an oozing swelling of the male genitals and if thy finger examines and the swelling is like [an unknown word] under thy fingers and it slips away then thou shalt say concerning it it is a swelling of the male genitals it is a disease which I will treat by an operation Thou shalt bandage him with grease and treat as one treats wounds in any limb of a man" Thus *Dr* Ebbell interprets as instructions for the operative treatment of a hydrocele

The greater portion of the treatise is however occupied with the appropriate remedies for the relief of symptoms such as cough, pain in the belly, worm-disease—Dr Ebbell believes that they knew of the worm which we call bilharzia, and also of the *Anchylostomum duodenale*—spitting of pus asthma, that is shortness of breath, dropsy, and so on And it is here that once more we find that there is no new thing under the heavens Among much which is obsolete and much that cannot now be understood, there are many of the drugs and minerals which the doctor of to-day still uses freely senna and castor oil, calamine and antimony, colocynth and hyoscyamus We read "Remedy to cause purgation senna pods and fruit of colocynth are ground fine, put on honey and eaten by the man and swallowed with sweet wine" A remedy for blisters on the limbs consists of pine tar, turpentine, an unknown substance, cuttle-bone, yellow ochre ground fine with water and applied as an ointment—and probably quite as efficacious as any modern prescription for a bullous eruption

Dr Ebbell and his publishers in Copenhagen and here have earned a debt of gratitude in thus enabling the modern profession to realise something of what we owe to the long line of our precursors which stretches out to the earliest dawn of history and the dim recesses of prehistoric ages

HOME CARE OF THE MENTAL PATIENT

FROM Holland, where much attention is paid to the home conditions and occupations of the patient with unbalanced mind, comes (in English)[1] a simple description of mental disorder designed for the lay rather than for the medical man The words "psychosis" and "neurosis" are never mentioned, but brief accounts of the common types of mental and neurotic abnormalities are given—too brief perhaps to be of much use to those who are struggling with the serious problem of an acutely ill or a chronically demented patient at home Dr Querido's clinical descriptions, though brief, are provocative He includes all the psychoneuroses under the general title "disharmonic personalities" and then divides them into "tyrants" and "shirkers" These terms are not, perhaps, inappropriate but we doubt whether it is wise to use them in a book for laymen, since they may well intensify the moral stigma often associated with these conditions It is to the trained rather than to the untrained attendants of mental patients that we would commend this book

CANCER FICTION

David Cannon was the leading surgeon in Manchester or some such place[2] He found that an implanted or spontaneous tumour in a rat could be cured by inoculating the animal with a living emulsion of cells from a rat tumour of lower virulence, especially if the inoculum were briefly titillated with weak X rays Applying these results to man, Cannon and his enthusiastic assistants, fortified with vast libations of tea, coffee, beer, and whisky, treated more than 100 cases of hopeless breast cancers in less than ten months and cured all of them, they also cured two melanotic sarcomas, one of which Cannon had, out of revenge produced by inoculation The results were finally announced to a crowded meeting in the great hall at B M.A. House which received them with great applause Such is the outline of a bright well told tale of hospital life in which there is nothing that is quite impossible and, making allowance for artistic *exaggeration*, little that is highly improbable It will amuse most doctors and nurses, and there will be a good deal of difference of opinion as to whether fiction is a fit vehicle for the subject matter

ADDRESSES AND ORIGINAL ARTICLES

THE EXPERIMENTAL OUTLOOK IN SURGERY *

BY SIR DAVID WILKIE M D F R C S
PROFESSOR OF SURGERY UNIVERSITY OF EDINBURGH

It is difficult to assign to discoveries in medicine their rightful place in order of importance Some would place the work of Lister in demonstrating the microbic nature of wound infection and the means of preventing it by chemical or other disinfection in the premier place both as a scientific and a beneficent discovery others might dwell on the discovery of the parasite of malaria and its mosquito borne spread as a contribution of world wide significance and yet others might point to Ehrlich s work on the therapy of syphilis, and with it certain tropical diseases as inaugurating a new era of chemotherapy

HARVEY

Epoch making and beneficent as all these discoveries have proved to be they have not the fundamental significance of Harvey s contribution The discovery that the blood circulated driven onwards by the heart, was epoch making in the truest sense of that oft ill used term but it was only one product of an outlook and a method which Harvey gave to medicine To be the father of a point of view of an approach to problems which change the whole basis of our study of disease is a real distinction but when that method is the simple logical search for truth applicable to any investigation of any problem of biology the distinction is outstanding and unique Harvey's method of careful unbiased and unfettered observation the formation of a hypothesis and the testing of this by experiment has not only stood the test of time but has formed the essential basis of the contributions of all his famous successors—John Hunter Claude Bernard Pasteur Koch and Lister

To have broken loose from the bondage of medieval theory and practice and to have done it with a simplicity and yet a completeness which still commands our admiration in this lay the genius of Harvey He showed a way of discovering scientific truths His method of anatomical observation of studies in comparative anatomy and on these of constructing a hypothesis had been the method of Vesalius and to some extent of Galen but those two had relied but little on experiment—the key stone of the arch Doremberg the French medical historian said of Harvey : He considers a long time and he finishes by seeing ; he makes few experiments but they are decisive ; he uses few arguments but they are conclusive What would not his methods yield to day if applied in their noble simplicity in the innumerable opportunities which surgery offers of making observations of disease in the living human being The need for cultivating the Harveian outlook is as great to day as ever it has been and especially for those who mean to practise surgery

HUNTER

John Hunter did for surgery what Harvey did for medicine as a whole Hunter is said to have read but few books choosing the face of Nature as his instructor and his guide One book however did not escape him and it is easy to imagine the thrill with which he must first have read De Motu Cordis and the fierce ambition that it kindled in his breast The insatiable curiosity and restless activity of this perfervid Scot claimed the whole realm of Nature as their field Following closely the method of Harvey but with tenfold the zeal and tireless energy Hunter observed questioned, experimented, and thus awakened once again the scientific urge which is the stimulus to progress

Hunter has often been described as the father of modern surgery As such he founded his family on the sure foundation of a never ending quest for scientific truth His search for the secrets of life and growth gave a new significance to medical study and raised the status of surgery from that of a mere handicraft to the dignity of a science The glamour of the discoveries of Pasteur and of Lister overshadowed for a period the true worth of Hunter's contributions of late however the importance of tissue growth and reaction the influence of internal secretions and of vitamins, the significance of the soil as opposed to the seed these have taken us back to Hunter and to his search for fundamentals

What a joy to Harvey would have been a day with Hunter in his animal sheds and his museum ! He would have gone home late to bed a tired but very thankful man having seen in full fruition the tree of scientific method which he planted just a hundred years before.

It was in the anatomical and surgical class room and in the experimental laboratory of Hunter that Jenner got the outlook and the point of view which led him to test the effect of inoculating cow pox as a safeguard against small pox We thus see that the experimental outlook in surgery gave the stimulus to Jenner s great experiment in practical immunity If this happy harmony of outlook had continued unabated through the years what a wealth of useful knowledge had been gained and what a burden of suffering avoided. Alas ! for a period the sciences of surgery and of infective disease parted company to meet again after more than half a century of wandering in the wilderness

Study of Infections

There is no more fascinating study than that of the rôle of surgery in the treatment of *infections* and the part played by infection in frustrating the curative efforts of surgery For the first three-quarters of the nineteenth century the heroic *attempts of* surgeons to aid the suffering by operation became *progressively more futile as the hospitals* became infected with germs of mounting virulence It was one of the greatest and most tragic experiments the world has ever seen this proof that germs become more virulent by successive passage through susceptible human beings When J Y Simpson advocated the burning of the old hospitals and the building of temporary wooden structures in their stead he was pronouncing a logical if somewhat heavy handed, method of exterminating virulent infections

If Semmelweis had but held on when he had convinced himself that by making the students coming from the dissecting rooms wash their hands in a solution of chloride of lime before examining pregnant women he could in great measure prevent puerperal septicæmia if he could have staged a crucial experiment as Pasteur did at Chartres, how willingly would Lister have handed him the palm as the greatest benefactor of mankind. Semmelweis had the great idea and, if he had not the philosophy to withstand the inevitable repercussion which the impact of a new idea elicits from the innate conservatism of the uninspired human mind, he must ever be regarded, with the sympathy due to the misunderstood, as the forerunner of a new age in surgery.

---

* A lecture delivered before the Harveian Society on March 11th 1937

Pasteur laid bare the secret. The successive steps in his work on fermentation, silkworm disease, anthrax, and rabies, the satisfying completeness of his proofs and the simplicity yet thoroughness of his experiments furnished the pattern and the implements for the experimental work on wound infection.

LISTER

When Lister, already with the idea in his mind, came to Edinburgh to study surgery under Syme, he was possessed with the thought that in the solution of this problem of wound infection lay the whole future of surgery. Several factors combined to favour his investigation. Firstly, as he repeatedly avowed, he found the atmosphere in Syme's clinique sympathetic and helpful in his work; secondly, he had already had some training in scientific methods and outlook; and thirdly, he was interested in and conversant with discoveries in the fundamental sciences and thus had read of Pasteur's remarkable experiments. Only the mind trained in the experimental method could appreciate the significance of Pasteur's work and the possibility of its application to the suppurating wounds and the pyæmia of the wards. As Sir Frederick Gowland Hopkins pointed out in his presidential address to the Royal Society, the fundamental sciences are the source from which clinical observation and clinical analysis must always derive their impulse for advance. It was in the laboratory of Pasteur that the germ theory of wound infection had its beginning; it was through the scientifically trained surgeon, versed in the literature of the fundamental sciences and capable of correlating and combining the bedside with the laboratory experiment, that the vital gap was bridged and the supreme benefit to suffering mankind conferred.

The care, the step by step advance, the personal attention to every detail of the proof, these characteristics of Lister's work were what impressed his students and the surgeons from abroad who visited his wards, both in Glasgow and in Edinburgh. His implicit faith in the victory of truth gave him the calm philosophic outlook which poor Semmelweis had lacked and which commanded attention, respect, and admiration from his students and from all but the most biased and petrified among his surgical contemporaries. It does not detract from Lister's immortal work for humanity any more than it does from Harvey's great induction, to say that it was not the work of one mind. "To perfect is to invent. All investigators inherit from their ancestors and Truth is the daughter of Time."

The discovery of the cause and the means of prevention of wound infection gave not only an immense impetus to helpful and curative surgery and an untold relief from suffering and death to those who needed operation, it gave new opportunity to both clinical and experimental research by removing one uncertain and complicating factor which heretofore had vitiated all observations and results.

The Rise of Abdominal Surgery

The history of abdominal surgery in pre-Listerian times has many interesting pages and gallant episodes. The intrepid ovariotomists, with Ephraim McDowell at their head, had in many instances been country surgeons, operating far from crowded cities and infected hospitals, and the hardy peritoneum had withstood in many cases the relatively avirulent infection introduced. The domestic type of cleanliness, practised by Lawson Tait, was so successful as almost to confuse the issue for others as it did for him. The demonstration by Lembert, also a country surgeon, that an inverting suture rendered the closure of intestinal wounds both simpler and safer, laid the foundation of gastro-intestinal surgery. Surgeons were waiting for the lifting of the ban that post-operative peritonitis had imposed. It was, therefore, not unnatural that in the early 'eighties of last century an immense amount of work should have been done on the surgery of abdominal diseases.

ALIMENTARY TRACT

The successful removal of tumours of the stomach or intestine demanded a technique, the perfection of which could only be attained by experiment, and to the patient and controlled work of Wölfler, Czerny, Gross, and Senn we owe successive steps in the building up of reliable and simple methods of anastomosis. That indefatigable student, Samuel Gross, did valuable experiments on the suture of wounds of the intestines, but it was Nicolas Senn who was the most fruitful worker among the early experimenters in gastro-intestinal anastomosis. Night after night he could be found at his experiments in a small laboratory constructed under the sidewalk of his home in Milwaukee. At medical meetings he always contributed personal experimental observations and brought with him the specimens from his experimental laboratory—a worthy descendant of Hunter and of Harvey.

In 1881—the annus mirabilis of abdominal surgery—Billroth's clinic in Vienna was the scene of the premières of many surgical procedures. Among these was partial gastrectomy for cancer, and gastro-jejunostomy, first performed by Wölfler on the suggestion of his assistant Nicoladoni in a case of irremovable carcinoma of the pyloric antrum. The zealous care with which Billroth supervised all these early operations, and the close collaboration which he encouraged between the experimental laboratory and hospital operating theatre, favoured the rapid strides which surgery made at this eventful time.

Mikulicz, one of Billroth's assistants, played a leading part in the development of abdominal surgery. As professor of surgery in Breslau, he was unceasing in his efforts to extend the scope, and especially to increase the safety, of abdominal operations. The exteriorisation of tumours of the colon and their removal by a two- or three-stage operation was introduced by Paul actually before it was by Mikulicz, and to both surgeons credit is due for a method which effected a great reduction in mortality. Mikulicz introduced the practice of giving nucleinic acid before operation to induce an artificial leucocytosis, proving by animal experiment that resistance to peritoneal infection is thereby raised. Later, in Edinburgh, it was shown that by combining the injection of vaccines of *Bacillus coli* and streptococci with the nuclein injections, the immunity to peritoneal infection could be further enhanced.

Pfannenstiel, in Kiel, showed that by injecting sterile olive oil into the peritoneum an increased local resistance to infection was brought about; indeed it became evident that any irritation or insult to the peritoneum called forth a reaction which was protective against subsequent infection. This fact constituted one of the main factors of safety in the two-stage abdominal operation in which the dangerous stage is left to be the second step

EMERGENCIES

Whilst the surgical treatment of certain acute abdominal conditions such as strangulated hernia goes back to antiquity the surgery of acute abdominal emergencies belongs to the post Listerian epoch. As such operations increased in number and as by correlation of operative findings with clinical symptoms diagnosis became more accurate there was a tendency to regard immediate operation as the panacea for all such conditions Continued clinical investigation linked up with experimental work has shown us that in certain conditions and at certain stages operation may be both meddlesome and harmful whilst in others every hour that operation is delayed adds to the risk of death

In obstruction of the bowel we have learnt to distinguish between the various fundamental types, and the cause of death in each and thus to put our treatment on a rational basis The realisation that in simple high intestinal obstruction the main lethal factor is loss of fluid and chlorides, and that if these be supplied in adequate amount life may be prolonged for weeks even if the obstruction be not relieved has made the administration of salt solution an essential first step in our treatment of such obstruction

We know that in closed loop obstruction or in strangulation the tendency to rapid necrosis and infection of the wall with gross perforation or bacterial permeation and peritonitis, makes not only the need for early operation clamant but the need for radical surgery clear A clinical impression that when in the least doubt it was wiser to resect a strangulated but possibly still viable loop has received abundant confirmation from the experimental laboratory Further in cases of strangulation it has been shown that the fluid exuding into the peritoneal cavity from the strangulated loop contains toxic elements and its removal by suction is desirable

On the other hand in inflammatory lesions within the abdomen the recourse to active surgical interference which was the rule thirty years ago has as the result of clear experimental evidence given place to a much more expectant and conservative régime In cases of pelvic inflammation in walled off appendicular inflammation of some days duration in acute cholecystitis and even in acute pancreatitis we tend to be conservative until we see the clear indication for active surgery

Surgery of Disordered Physiology

Perhaps the most striking development in twentieth century surgery is the extension of the field from the treatment of trauma deformity tumour growth and infection to that of disordered physiological action

First in importance and frequency is the resection of the thyroid gland for various forms of toxic goitre To Kocher of Berne we owe the pioneer work in thyroid surgery He reported the condition of cachexia strumipriva which followed total extirpation of the thyroid gland and together with Reverdin with Schiff and with Horsley in this country carried out those experiments that may be said to form the real starting point of our knowledge of the ductless glands The story of the first very hæmorrhagic and dangerous operations for exophthalmic goitre which had resisted all forms of medical treatment; the frequent post operative deaths in a crisis of thyrotoxicosis complicated by blood loss the evolution of pre-operative measures and operative technique by Crile and Charles Mayo and finally the demonstration of the immense value of iodine as a pre-operative medicament by Plummer the earlier operation and the vanishing mortality these facts form a romance in surgery Indeed so great has been the success of subtotal thyroidectomy for toxic goitre—this colossal surgical experiment on the human being—that it has I think, probably retarded the investigation of the essential nature of this disease. The fame of the operation will be fleeting and will seem strange indeed to our successors That some means of controlling thyroid activity short of the heavy handed method of surgical resection will be found cannot be doubted I trust it may be found in some surgical research department

The removal of the thyroid gland in cases of cardiac disease with decompensation or angina is another example of using physiological knowledge to mitigate the effects of disease. The thyroid being regarded as the metabolic pacemaker and cardiac decompensation and angina both being regarded as evidences that the heart function is on a lower plane than that of the body as a whole Blumgart argued that by removing the thyroid gland and so lowering metabolism the body would be brought down to the level of the heart The results following this operation particularly in cases of angina, are such as to warrant a continued trial.

A. von Eiselsberg who for so long held the chair of surgery in Vienna, was an outstanding example of that band of famous surgeons who have graduated in the experimental field His early work on tetany and the parathyroids, and on the pituitary gland, not only marked him out as a keen observer and a highly skilled technician but formed the basis for a new avenue of advance in surgery

The successful removal of simple parathyroid tumours in cases of generalised osteitis fibrosa cystica of tumours of the islets of Langerhans in cases of recurring attacks of hypoglycæmia and of adrenal tumours in Cushing's syndrome are all examples of a subtler type of surgery based on a knowledge of the fundamental sciences

The surgery of the sympathetic nervous system starting with the work of Leriche on peripheral vascular disorders extended to the relief of angina pectoris of incoordinated action in the colon in Hirschsprung's disease and later to achalasia of the œsophagus this branch of surgical enterprise is still in its experimental stage and the rigid standards of the experimental laboratory are necessary in assessing its results

It is becoming increasingly evident that certain lesions that up till now have been regarded as requiring operative surgery will some time and possibly quite soon come within the sphere of hormone therapy Undescended testicle in the young boy has been shown to descend after repeated administration of gonadotropic hormone Some encouraging results have already been obtained in cases of senile enlargement of the prostate by the injection of testosterone or male hormone Irregular involution or cystic disease of the breast has yielded to treatment with follicular hormone It is obvious that in future our treatment of many disorders will be more subtle and less radical but in this wide and fascinating field of hormone therapy it is obvious that the need for the most careful scientific work and for the records of the trained observer is very great There is a real danger of practice leaving proof behind and the practitioner of medicine using hormone therapy without real knowledge or due discrimination.

Cellular Surgery

To Halsted, perhaps more than to any other man, do we owe the advances in surgery of the last three decades. Halsted had a long apprenticeship in the experimental laboratory where he did fundamental work. His researches on the healing of wounds proved to him the importance of accurate apposition of wound surfaces, leaving no dead space, and the equal importance of leaving a minimum of bruised or dead tissue in the wound, no mass ligatures, no forcible retraction, no ragged edges. He showed that the body will combat successfully a certain amount of infection in a wound if these rules be observed. Kocher was working on the same lines and was, in Europe, training a band of surgeons to respect the living cell and the fragile tissues just as Halsted was founding in America a school of meticulous and delicate surgery which has made his pupils the foremost surgeons of their day.

Macewen, Horsley, and Kocher did pioneer work in cerebro-spinal surgery, but it was the remarkable advances based on Halsted's technique, made by Cushing and his pupils that opened one of the great chapters in surgical history. The demonstration that if blood and fluid loss be minimised, and what does occur be replaced, an operation within the skull may be carried on for even eight or nine hours without dangerous deterioration in the patient's general condition, has enlarged the field of cerebro-spinal surgery to a degree undreamed of thirty years ago. The very greatest credit is due to Cushing and to all his pupils for combining the most searching preliminary investigations with delicate, yet enterprising, operative methods. There is no field where greater promise still remains for furthering knowledge of function, no less than of extending the bounds of radical surgery, than in the cerebro-spinal system, and no band of men with the experimental outlook more fully developed than the group of highly skilled surgeons who have devoted their lives to this difficult and exacting specialty.

In this country the movement in surgical thought and practice, initiated by Halsted, reached its zenith in Moynihan, whose respect for living tissues was evinced at every turn and who brought not only gentleness but art to bear on every branch of operative surgery. Just as Virchow was the founder of cellular pathology so these men were the founders of cellular surgery. The surgeon who shrinks from damaging one cell more than is necessary is not only going to have smooth and kindly healing in the wounds he must needs inflict, but is to save his patients some degree of the toxæmia that inevitably results from the autolysis of damaged cells.

When we think of cells let us not visualise the fixed and stained structures of the histological laboratory. Reagents confer on colloidal matter an appearance which differs in most cases in kind and in some cases in degree from the initial structure. Let us think rather of the living cell as we have seen it in the tissue culture medium, a mobile mass, charged with a restless energy, as a "mixture of colloidal slimes of varying degrees of fluidity," as a body like the protozoön which may disrupt explosively if the surface membrane be ruptured. If we think thus of the tissues we handle we will instinctively acquire that reverence for those cellular structures—essential parts of that infinitely complex mechanism, the human body—which will, in Moynihan's words, make every operation a veritable sacrament.

Surgery in Infections

In no branch of surgery have the lessons of the laboratory and the experimental outlook been so salutary as in that of acute infective lesions. The study of the inflammatory process, and the reaction of the body to infection as seen in lowly forms of life and in the laboratory animal, led to an ever increasing respect for the capacity of the host to deal unaided with infection. Metchnikoff's "Comparative Pathology of Inflammation" is a surgical primer. Occasionally a very virulent infection will paralyse defence and sweep all barriers aside. If trauma be added to infection a handicap is surely added to the work of the defence. When infection is established the rational policy of treatment is defensive and conservative, local offensive measures to eradicate infection usually being ineffective for this object and mischievous by breaking clumsily through Nature's barriers.

The lessons in immunity, in which the enterprising science of bacteriology has been so fruitful, all point to a supporting and conservative line of treatment as the most helpful during the early acute phases of local infections. The passive hyperæmic treatment of August Bier, based on an exemplary piece of clinical research, has stood the test of time and is one of the simplest and most valuable methods we possess of treating virulent acute infections. The damming back the tide of infection until the immunity reaction is under way, the aid to the local defensive mechanism and the relief of pain, which properly applied passive hyperæmia procures, will ensure for it a lasting place among therapeutic agents.

The return to the conservative line of treatment for diffuse peritonitis—starvation, morphia, local heat, fluid by intravenous drip, and an empty stomach by an in-dwelling duodenal tube—has lowered the mortality and confirmed the findings of the laboratory.

The occlusive method of treating acute infective lesions—e.g., boils, carbuncles, and even osteomyelitis—has been vindicated by results, and forms an interesting chapter in surgical history—the conversion of the surgeon from the mechanical to the biological point of view.

The valuable work leading to the improvement of antitoxic sera has placed in our hands a telling weapon of defence if used in sufficient dosage at an early stage, before toxic degenerative changes in vital organs have occurred. The discovery of a drug, Prontosil, which will destroy micro-organisms in vivo without poisoning the tissues, is a very significant observation fulfilling in some measure the long-sought ideal of a therapia sterilizans magna. These advances all tend to show that the biologically minded surgeon who has reaped the lessons of immunity and has graduated in the fundamental sciences has still many bloodless but no less glorious victories to win.

Need for Trained Observers

Surgery offers opportunities, which are denied to medicine, of seeing pathology in the making and in its living form. Too often at operation the surgeon is more concerned with what he can do than with what he can see. We see but what we look for, and only the dissatisfied spirit and the strictly truthful, unbiased and yet observant mind can see the new and appreciate the significance of what is seen. To train surgeons whose chief interest is the science rather than the handicraft of surgery is the leading need of to-day That a part of this training is best acquired in the experimental laboratory is to my mind beyond doubt The planning of experiments the elimination of all the complicating factors which almost inevitably arise to confuse the issue the need for meticulous care for accurate records and for adequate control all these factors combine to sharpen both the outlook and the critical faculty of the young surgeon He may make no discovery nor lay bare any fresh truth but the training will at least help to prevent him from establishing false doctrines and practices based on loose or faulty observation. Is not the difficulty in establishing a new truth the fact that the field is littered and encumbered by the prejudice and practice instituted and upheld by unscientific men?

When twelve years ago we opened a department of experimental surgery in Edinburgh it was with the object of training surgical observers no less than of directly advancing scientific truth To only a few is given that intuition which is the indispensable cutting edge of scientific as well as of intellectual inquiry but to many may be given that training and outlook which make reception and appreciation of scientific truth both ready and responsive Meetings and discussions form an essential feature of a surgical research department To present the results of a piece of work be it from the hospital or the laboratory before a group of scientific colleagues demands the crystallisation of ideas a logical sequence both in proof and in presentation and an elimination of non-essentials invaluable lessons in the training of a young clinical teacher Nothing could be more in keeping with the spirit of Harvey than the friendly rivalry in investigative work of the young men in a medical school. Without this spirit in its junior men the future of a school is bare of promise and of hope

The development in the Royal College of Surgeons of England of a centre of experimental surgical research and the Buckston Browne experimental farm at Downe both under the able and enterprising direction of Dr John Beattie is the final proof that we in this country now recognise the need for the experimental outlook in surgery

The study of clinical science developed and fostered with such success by Sir Thomas Lewis has so far mainly concerned itself with the problems of internal medicine Intensive clinical study can furnish data which the laboratory cannot provide and when furnished there is no need for translation to the human form The same degree of concentrated study applied to the pre-operative and post-operative phenomena in surgical cases offers rich promise of significant results If this clinical study can at the same time be linked-up and correlated with laboratory experiment we would seem to have a very powerful instrument for furthering our knowledge of disease

Specialism

It would appear that we have reached a stage in the advance of medicine at which without intensive study of one field it is difficult to contribute anything that is new to the sum of knowledge Convincing evidence could be led to prove how concentration makes for progress—e g how in disease of the urinary system in which at one time diagnosis was notoriously inaccurate and vague specialisation and focused ingenuity have now made diagnosis in this field the most accurate in the whole domain of surgery In regard to neurological surgery and to surgery of the chest similar evidence could be produced. It is very desirable however and especially in our teaching schools that we all begin our training on the broadest lines remembering that the height of the pyramid is governed largely by the breadth of its base

Most of the important advances in medicine even in recent years have been systemic and not regional in their scope and have been contributed by workers in the wider field. The comparative sterility of effort of such numbers of our intensive clinical workers in their narrow fields is without question a lack of education and training in the fundamental sciences

It may well be that the discoveries of medical science in the next few years will cut horizontally through many of our specialties and a reorientation of the field may be desirable The clear cut distinction between medicine and surgery may go and the operating physician in various specialties may find new lines for the advance of knowledge. As the need of the knife becomes less as assuredly it will the need for breadth of training in the surgeon will increase with equal steps. Possibly in these far-off emancipated days the disparity of remuneration for skilled advice and operative treatment will be less flagrant than it is to-day

Present Needs of Research

For some years now there has been a tendency in some quarters to regard the greatest need of research in this country as endowment If we could but have research institutes with handsome scholarships for younger workers science would flourish and all would be well! I believe this view to be fallacious It is true that accommodation and salaries are necessary but they are there already It is men and ideas that are lacking Modern research does doubtless require some more elaborate apparatus than when simpler problems were being solved but as Claude Bernard said Experimenters do not grow great by the number and complexity of the instruments they use it is really the other way The great experimenters made great discoveries by means of simple instruments

What we require most of all to-day is to encourage the occasional student who has the flair for investigative work to pursue his bent and not be led off to practice The man with ideas and the urge to test them is an asset which we never can afford to waste He should be trained and encouraged. Men are incomparably more valuable than institutes The man without the institute will probably somehow carry on his work the institute without the man is a standing mockery Even the method of experiment may be vain in the hands of the uninspired As Bernard said The experimental method cannot give new and fruitful ideas to those who have none it can only serve to guide the ideas of men who have them to direct their ideas and to develop them so as to get the best possible results As only what has been sown in the ground will ever grow in it so nothing will be developed by the experimental method except the ideas submitted to it The method itself gives birth to nothing

The scheme of the Medical Research Council for awarding studentships and fellowships in research the former for the training of likely men in methods of investigation the latter for continuing in research those who have proved their worth, t
offers promise of catching at a ec
age the young men with investigative
each of our medical schools th
nidus where the young man
and grow we should have t

Clinical Refreshment

The advances in pure science and the triumphs of the laboratory have been so striking in the past decade, the methods used have become so specialised and intricate, that the laboratory worker has tended to become a man apart, whose interests, indeed whose language and vocabulary, are little understood by the clinician For the advance of medicine I believe that this is a real misfortune Whilst not denying that every discovery of truth is valuable and may sooner or later contribute directly or indirectly to human welfare, I am impressed by the fact that the most beneficent researches have been stimulated by some clinical incentive and the call of human need Every one of Pasteur's great discoveries was based on ad hoc work, a practical need giving the urge and stimulus to continued effort The discovery of insulin had a clinical beginning and furnishes an excellent example of the value of correlated laboratory and clinical research

I believe that the work of many of our laboratories would be revivified and made more fruitful if their highly skilled technical workers could be refreshed by contact with the problems which confront us daily in the medical and surgical wards of all our teaching hospitals A regular system of ward rounds at stated periods and special consultations on unusual cases, where the laboratory workers become aware of the practical problems of the clinician and the latter learn not only new facts of scientific import but the need to maintain a high and uniform standard of observation and of record, such a system although difficult to organise would, I am sure, be fruitful in result

De Generatione

Harvey's work on the developing ovum was not perhaps on a par with his great discovery but it showed his sustained fondness for a subject which in these latter days has acquired peculiar interest and importance The microscopic study of the early ovum and later the reconstructive method of investigation have given us much information on the nature and the order of the developmental process But what delight to both Harvey and to Hunter would the researches in experimental embryology of the last two decades have brought! The work of Driesch, of Spemann, of Holtfreter, of Needham and Waddington has not only supplied evidence of intense academic interest but has given us a possible clue to the understanding of malignant tumour growth Spemann showed in the case of the newt that up to a certain stage of gastrulation the fates of most of the embryonic regions are not irrevocably determined A piece of presumptive neural tube material removed from one embryo and grafted into another will turn into external gills if it happen to be grafted into the presumptive gill region of the latter Contrariwise a piece of presumptive skin if grafted into a suitable region of the presumptive nerve tube of a second embryo will in due course develop into brain and spinal cord Up to this stage of gastrulation the cells of various regions are still plastic or pluripotent even to the extent of mesoderm and ectoderm being interchangeable This early period of plasticity is followed by one of rigidity, when a graft will continue to differentiate according to its innate determination and not in accordance with the new situation in which it has artificially been placed One region of the amphibian embryo is not plastic during the early period of development, this is the region of the dorsal lip of the blastopore When this lip of the blastopore of the newt *Triton cristatus* was transplanted into the indifferent ectoderm of an embryo of *Triton tæniatus*, both in the early gastrula stage, it induced the formation of a new embryonic axis—i e, two embryos were produced where normally one should have been formed Spemann called this centre in the dorsal lip of the blastopore the "organisation centre" It was then shown that even if the transplanted tissue was crushed and disorganised it could still organise the constituent morphological parts of a second embryo suggesting that the organiser was chemical in nature

The substance retained its power if narcotised or even if exposed to heat Whilst in the living state only this one area possesses organiser properties, other areas if killed, boiled, or denatured by alcohol possess inductor capacity

This organiser hormone was then shown to be sterolic in character and was not even specific for the species of animal It came into line with the compounds also of sterol like structure (*a*) the sex hormones, (*b*) the cancer producing hydrocarbons, and (*c*) vitamin D When it was shown by Waddington and Needham that the implantation of some of the synthetic hydrocarbons used by Kennaway and Cook into the newt gastrula caused the induction of perfect neural tubes, the lack of specificity of hormones was definitely proved.

In the process of development we have now therefore the conception of a sterol like substance being liberated at a given point in the developing system and radiating its organising power from that spot The initiation of wound healing probably depends on a similar chemical stimulus In fact it has been said "the plans of living systems are written in chemical molecular structure, a language with a great wealth of expression"

How far this exciting [illegible] surgery of the young embryo will take us as yet we cannot say, but it is obvious that a new and exciting chapter has opened de generatione

Ex Corde Caritas

Harvey bequeathed to the profession a lesson of another order to that of his discovery in physiology—his injunction to his professional brethren to meet on friendly social terms, to observe that consideration for one another's interests as conduces to harmony and befits the dignity of a great profession To Harvey we owe the inspiration of our great societies, and as their meetings play no small part in maintaining the standard and furthering the science of medicine we must ever hold his name in high esteem in our gatherings and in our colleges

The good name of British surgery, which never stood higher than in the past three decades of its history, owes much to the policy of sharing knowledge and experience, of abandoning the parochially minded exclusiveness of individual schools, of travel, of seeing each other's methods, and of encouraging the younger men to pursue investigative work The various travelling clubs, the Association of Surgeons, the broadened scope and outlook of the Royal Colleges, these are all in keeping with Harvey's wish for concord, mutual betterment, and friendliness That at our meetings an ever increasing value should be placed on accurate observation, logical deduction and, where possible, on proof by controlled experiment, that clear thinking and thus simple, terse, and clear expression should be the standards we demand, these must be our perennial tribute to the memory of one who set for all time an example of the value of experiment in medicine and of dignity, of amity, and of mutual friendliness among the members of a great profession

THE BLOOD PRESSURE IN THE YEARS FOLLOWING RECOVERY FROM CORONARY THROMBOSIS

BY J H PALMER, M D McGill M R C P Lond
ASSOCIATE IN MEDICINE, ROYAL VICTORIA HOSPITAL, MONTREAL, CANADA

(From the Cardiac Department of the London Hospital)

In the past twenty years there have been many references to the fall in blood pressure that is a prominent feature of the period immediately following the onset of an attack of coronary thrombosis but few to its behaviour in the months and years after survival The subject seems worthy of detailed study and the present investigation was primarily undertaken in an endeavour to plot from a representative group the actual course of the blood pressure in the years following the attack At the same time a study was made of the incidence of hypertension in coronary thrombosis

GENERAL DESCRIPTION OF CASES STUDIED

The series comprised 212 patients all of whom had survived the attack for at least three months and many for several years They were collected chiefly from the records of the cardiac department of the London Hospital and from a consulting practice; a few are from the National Hospital for Diseases of the Heart There were 192 males and 20 females whose distribution according to age is set out in Table I Those selected for the series were such as were found to have blood pressure records extending over a period of at least a few months after coronary thrombosis The average length of time elapsing between the onset of the attack and the end of the period of observation was 4 15 years Almost half the series (102 cases) are still under observation at the time of writing and 65 cases almost a third are known to have died The remaining 45 could not be traced further after having been followed for various lengths of time almost two thirds of these disappeared during the first two years The patients were drawn from all social classes and are believed to present a fair picture of the whole group of survivors

TABLE I

Distribution of 212 Patients with Coronary Thrombosis According to Sex and Age at Time of First Attack

Age-group	Male.	Female.	Total No.	Total Per cent.
Under 40	1 (aged 20)		1	0 5
40–49	36	1	37	17 4
50–59	79	14	93	43·9
60–69	59	4	63	29·7
70–79	16	1	17	8·0
Over 80	1 (aged 81)		1	0 5
Totals	192 (90 1)	20 (9 9%)	212	100·0

This inquiry was a clinical one and therefore subject to certain limitations Chief among these was that the small number of necropsies made it necessary to rely upon clinical diagnosis Thus there were not included any of the silent cases that have been found in at least two necropsy series (Gille and Rykert 1935 Saphir, Priest Hamburger and Katz 1935) to comprise more than a third of the total number Besides the invariable history of pain of cardiac distribution lasting for at least an hour and accompanied by some shock the following conclusive signs were found in 174 (82 per cent) of our patients pericardial rub in 15 fever or leucocytosis in 55; electrocardiographic changes in the Q R S complex, S–T interval or T wave occurring over weeks or months in 146 and low systolic pressure in 34 Having regard to the fact that rest in bed alone will cause a considerable drop in blood pressure (Addis 1922) this last sign was used as corroborative evidence only when there was found a systolic reading below 100 mm Hg or else a reading less than two thirds that of others taken within 6 months The finding of incidental disease did not exclude a case from the series

INCIDENCE OF HYPERTENSION IN PUBLISHED SERIES

Figures showing the true incidence of hypertension before coronary thrombosis are difficult to obtain Most patients do not seek medical advice until after the attack and it was probably during this early period that many of the blood pressure readings were made in the reported cases assembled in Table II As most often at that time the blood pressure falls and only very exceptionally rises for a brief period during the first day or two (Hochrein 1932) it follows that these figures tell only part of the story The association of lowering of the blood pressure with advanced coronary sclerosis but without clinical evidence of thrombosis has been frequently noted (Fahr 1935 Bell and Clawson 1928 Horine Weiss and Beard 1932), so that the finding of a normal pressure before the attack does not rule out an earlier hypertension It is not the purpose of this paper to discuss whether this drop is due to an effect on the myocardium or is part of a general state preceding arterial thrombosis; in old people it has been observed to precede arterial thrombosis in other parts of the body (Dumas 1925) Of the present series 15 had had blood pressure readings over a period of several years before the attack the last record being in the year immediately preceding it; although the average tendency was only slightly downwards it is significant that in 3 (20 per cent) this last reading was normal despite previous hypertension

TABLE II

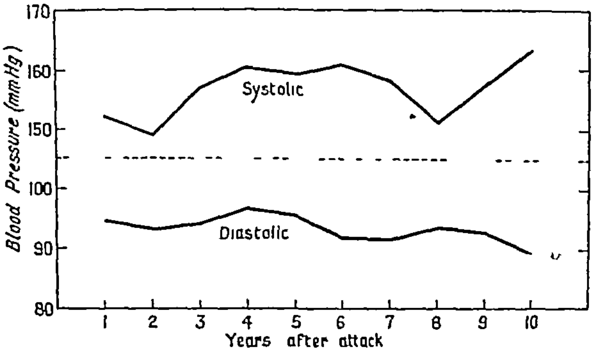
Incidence of Known Hypertension in Patients with Coronary Thrombosis

Authors.	Criteria of hypertension (mm of Hg)	Cases of coronary thrombosis.	Cases of hypertension	Incidence of hypertension per cent.
Barnes and Ball	S 150 or D 100	42	24	57
Boas and Donner	S 150	57		25
Conner and Holt	None given	271	93	35
Cowan and Ritchie	S 150	58	28	48
Eschbach	None given	50	*	75
Levine.	S 150 or D 100	148	44	30
White and Bland	S 160 or D 110	200	50	25
Present series.	S 160 or D 100	212	155	73

* Readings at first examination after attack.

The incidence of high blood pressure in cases destined to get coronary thrombosis is probably not different from that in coronary arterio-sclerosis as a whole

Evans, Ambler and Dodson (1933) in a review of 507 autopsies on cases of coronary disease all of which showed recent coronary occlusion, evidence of healed infarction, or diffuse myocardial fibrosis, found almost invariably cardiac hypertrophy, chiefly of the left ventricle and presumably due to hypertension In 136 cases that died from coronary disease, Bell and Clawson (1928) found satisfactory evidence that approximately 68 per cent were associated with hypertension (systolic pressure of 150 mm) Fahr (1935) discusses the findings of Bell and Clawson in 420 cases of primary hypertension arguing from the finding that 90 per cent of the hearts of all patients dying from hypertension show some coronary arterio sclerosis, and that Bell and Clawson's criteria for hypertrophy (450 g and 500 g respectively for female and male) are unnecessarily severe, he concluded that, according to his own standards, actually 90 per cent of their coronary sclerosis cases showed evidence of association with hypertension Bell (1934) himself puts it at 75 per cent Besides quoting what he found to be the incidence of hypertension based on actual readings (Table II), Levine (1929) estimated that it had been present in the majority of his cases, while Conner and Holt (1930) formed the impression that coronary thrombosis was found among persons with normal blood pressure almost as frequently as among those with hypertension High blood pressure was found by Fahr (1935) in 80 per cent of his cases of coronary sclerosis, and he says that in his opinion "it can conservatively be estimated that 75 per cent of all patients with coronary disease at some time or other have had high blood pressure" (criteria 150/90 mm)



Average course of systolic and diastolic blood pressures during the ten years after a first attack of coronary thrombosis from observations in 212 cases (see Table II)

INCIDENCE OF HYPERTENSION IN PRESENT SERIES

For the purpose of the present investigation the hypertension level was arbitrarily fixed at 160 mm Hg systolic and/or 100 mm diastolic (Diastolic pressure was read at the fourth phase, namely, the point at which the loud snapping sounds become muffled) Most clinicians will agree that this level is sufficiently high, yet many observers, particularly American, are inclined to believe that the upper limit of normal is lower than this The evidence derived from the authors already quoted, if it were expressed in figures based on this standard (160/100 mm) would probably indicate the incidence of hypertension in coronary thrombosis subjects as being from 60 to 70 per cent

In the series of 212 cases here investigated the hypertensive group numbered 155, 73 per cent of the total The group consisted of all those that at any time during the period of observation, either prior to or subsequent to the attack, showed a reading at or higher than the levels quoted above—i e , 160 mm systolic or 100 mm diastolic There were 30 cases included though hypertension had been observed on one occasion only, but borderline readings were additionally obtained in most of them Any error here is more than counterbalanced by the fact that the non hypertensive group undoubtedly contained cases, which, if readings before the attack had been available, would be found then to have had raised pressure , as evidence in support of this 24 (42 per cent) of the non hypertensive group of 57 cases had cardiac enlargement

The finding that 73 per cent of the whole series gave actual hypertensive readings is considerably in excess of the reported figures quoted in Table II This is largely due to the fact that those series included cases that died shortly after the attack, while in mine high readings were not recorded in 32 of the 155 cases until after the lapse of at least a year, and in one case not until after 14 years That the percentage of previous hypertensives closely approximates to this figure for the whole series is supported by the finding that in the smaller group of 66 cases in which the blood pressure before the attack was actually known, it had been high in 45 (68 per cent) Further evidence is forthcoming from a separate group of 100 unselected patients with angina of effort—presumptive evidence of coronary sclerosis—in none of whom, so far as is known, there had ever been an attack of coronary thrombosis, here the incidence of hypertension was 69 per cent

In 192 cases records taken during the year immediately after the attack were available Among these, 104 (54 per cent) showed hypertensive readings during this period, and in 28 (14 6 per cent) the systolic blood pressure reached or exceeded 200 mm These figures understate the situation, for in 32 of the group the only available readings were made during the month immediately following the attack, when the blood pressure need not necessarily have recovered from the acute stage The percentage of cases showing hypertension in each succeeding year increased fairly steadily until in the 10th year it was 72 per cent

Age and Sex—Hypertension was found in only 37 per cent of the group under 50 years of age at the time of the attack, and in 78–84 per cent of those in the sixth, seventh, and eighth decades All the female patients, except one who was under 50, were hypertensives

COURSE OF THE BLOOD PRESSURE FOLLOWING RECOVERY FROM THE ATTACK

In compiling a chart to show the course of the blood pressure for the whole series (see Figure and Table III), an average was first taken of all the records available in an individual case at any time during each separate year following the attack If only one reading were available for the year in question, that was used From these figures the average during each year

TABLE III

Average Course of Blood Pressure After Coronary Thrombosis (212 *Cases*)

* Exclusive of 1st month following attack
Syst = systolic. Diast. = diastolic.

was computed for 10 years the number of observations in patients surviving longer than this is too small to give accurate conclusions The first year figures do not include readings taken during the month immediately following the onset of the attack Similarly where further attacks of coronary thrombosis occurred all readings made within the month subsequent to such attacks were excluded this was done so as not to distort the curve during the later years when the total number of cases was not large Even so the noticeable drop during the eighth year was doubtless due to the fact that almost half the cases on which was based the average for that year had recently sustained another attack Table III also indicates the number of cases contributing to the average for each year Unfortunately records for more than two or three consecutive years were available in only a few cases Although this is a defect in that the averages from year to year do not necessarily include the same cases it is felt that there is a large enough number to compensate for this In the whole series 96 per cent first contributed to the chart not later than the second year and thus the possibility was eliminated of late introduction becoming a disturbing factor

During the ten year period the average systolic blood pressure rose from 152 2 mm during the first year (not including the month immediately following the attack) to 163 6 mm during the tenth year The steepest rise was during the first two years and probably indicates recovery from the attack The diastolic pressure showed little change during the

whole period, but in the main a tendency to drop slightly

It has been shown that in healthy persons (Symonds 1923), and in groups of unselected patients (Gager 1930), there is a gradual but steady rise in systolic pressure with increasing age This rise is maintained until the ninth decade (Bowes 1917, Richter 1925) In healthy adults whose average pressure is low the increase is from 1 to 5 mm of mercury every ten years In unselected groups containing a fair proportion of hypertensives the average pressure is of course higher, and the increase during each decade is rather more These findings make it highly probable that the slight rise found in the average systolic pressure in the present series is little if any more than is normally expected as a result of increasing age The slightly lower diastolic pressure at the end of the ten year period is commonly found after middle age, and is believed to be due to the progressive loss of elasticity in the aorta and great vessels resulting from arterio sclerosis (Wiggers 1932)

If it be accepted (see below) that the average blood pressure for the whole series before the attack is in the neighbourhood of 170/100 mm , it is obvious that *on the average* the prior level is not reached during the ten years after it Yet it was found that in 20 of the 66 cases in which the prior height of the blood pressure was known, this level was actually reached or exceeded There were 4 of the 20 who were non-hypertensives, and of the remaining 16 there were only 3 in which the subsequent rise was greatly in excess of the record before the attack

EFFECT OF AGE

When the course of the blood pressure was plotted by age groups, it was found that the levels of both the systolic and diastolic pressures of those patients in whom the onset of the attack was in the 5th decade were appreciable lower throughout than those of the whole series The curves for the 6th, 7th, and 8th decades on the other hand followed each other closely for the first few years, after which there was a tendency for the older groups to rise more abruptly than the younger ones

THE BLOOD PRESSURE IN CASES WITH READINGS BEFORE THE ATTACK

In Table IV may be followed the course of the blood pressure in a representative group of patients in whom the blood pressure before the attack had been recorded , subsequent records could then be compared with these previous ones The figures in the table show the averages (to the nearest 5 mm of mercury) of all blood pressure records taken during each year indicated , in compiling the Figure, all records taken within a month following an attack were omitted,

There were 66 cases in the group Hypertension before the attack was found in 45 (68 per cent), the systolic pressure in 16 cases having been 200 mm or higher The average prior height of the blood pressure was 171/99 mm A trial chart prepared from the 66 cases in the same manner as was adopted in compiling the Figure revealed that for the first four years (during which period the number of cases was large enough for purposes of comparison) the height and course of the blood pressure followed so closely that of the whole series as to suggest that the levels just quoted, namely, 171/99 mm , were actually those of the whole series before the attack Further evidence in support of this comes from the separate group of 100 cases of angina pectoris referred to above where the average height proved to be 170/98 mm

The lowest levels recorded during the first month after the attack are also shown in Table IV These were not necessarily made at the time of the greatest drop To investigate the blood pressure during the first month was not one of the purposes of the present investigation, but observations on 144 of the whole series during this period led to the general impression that, for cases of coronary thrombosis surviving the attack, the behaviour of the blood pressure during the first month is without ultimate significance This has also been the experience of Hochrein and Schneyer (1936)

In only 5 out of 39 cases of prior hypertension did the blood pressure fail to regain hypertensive levels within two years of the attack In 14 cases out of the 66 in the group, the height of the systolic blood pressure was at some time following the attack known to have exceeded the prior height by more than 10 mm , 4 of these cases, however, were never hypertensive

SUMMARY

An analysis was made of the blood-pressure findings in 212 patients who survived an attack of coronary thrombosis by at least three months The incidence of hypertension (160 mm systolic and/or 100 mm diastolic) as determined by readings made before or at any time after the attack was found to be 73 per cent More than half the cases showed hypertension during the first year The hypertensive group included 37 per cent of those aged under fifty, and 78–84 per cent of those in the next three decades of life at the time of the attack All except one of the 20 female patients were hypertensives

The average course of the blood pressure during ten years after coronary thrombosis (not including the first month following the attack) has been plotted. The systolic pressure showed a slight rise during this period while the diastolic showed a slight fall

Evidence is adduced to show that the average blood pressure for the series before the attack was probably about 170/100 Although on the average the prior levels were not regained during the ten year period, they were in a few cases actually exceeded

I am indebted to Dr John Parkinson physician to the cardiac department of the London Hospital for placing his case notes at my disposal, and for his helpful advice in the preparation of this paper

ACUTE DIFFUSE NON-SUPPURATIVE ENCEPHALITIS

TWO CASES DESCRIBED

By R. Lawford Knaggs
CONSULTING SURGEON, LEEDS GENERAL INFIRMARY

After a long absence from active professional work a certain reluctance to venture upon ground that is becoming more and more unfamiliar will be readily understood, but as the only person fully acquainted with the details of the following remarkable case it is incumbent upon me to record it.

Case 1.—A boy, aged 10, was admitted to the Leeds General Infirmary on March 7th, 1912. His parents stated that he had suffered from influenza before Christmas and since then he had not looked well. Except for rheumatism in his hands and feet he had been quite normal till the week before admission. Then a weakness of his right hand caused difficulty in writing and awkwardness in fastening his collar. Occasionally the fingers became flexed into the palm and could only be extended forcibly. On March 7th at 11 A.M. he was playing football when a playmate struck him on the nose. He ran a few yards, then fell and became unconscious. He was seen by Dr. Rock, who made the following notes, which he sent with the patient to the infirmary: "11.30 A.M. unconscious; left eye firmly closed and pupil contracted to a pin point; right eye wide open and pupil fully dilated; upper right eyelid in a state of continuous convulsive movement; right arm the same. Face deep maroon colour; breathing regular, 10 per minute, stertorous; pulse-rate 60; no vomiting. Some frothy mucus was twice ejected, but this was attributed to some neat brandy irritating his larynx."

On admission he was still unconscious; both eyes were wide open and usually deviated to the right; pupils dilated and slightly sensitive to light. The face was congested, conjunctivæ suffused, and the left angle of the mouth was seen to twitch. Both arms were rigid and there was frequent twitching of the right arm and leg. Pulse of good volume, rate about 100; temperature subnormal. As he was being examined the breathing was noticed to become more and more irregular in rhythm and the stertor more pronounced. In a few more minutes it was evident the Cheyne-Stokes type of respiration was developing. Both optic discs were then found to be swollen and pale and their edges blurred.

Operation.—It was quite clear that the compression was increasing and that relief was urgently necessary, so he was at once taken to the theatre and decompression operations over the right and left motor areas were carried out. The gaps made in the cranial vault were roughly circular and 2½–3 in. in diameter. On the left side, which was first attacked, the dura bulged and there was no pulsation, but when the dura was slit crucially the soft brain bulged till it had risen quite an inch or more above the surrounding bony surface. The pia arachnoid was œdematous and the cerebro-spinal fluid that escaped was clear. On the right side the protrusion was not so pronounced, but the intracranial pressure had no doubt been partially relieved by the first decompression. From the moment of his fall to the conclusion of the operations only 4 hours elapsed.

Progress.—The next morning it was evident that the relief of tension had led to considerable improvement. Though he did not recognise either his father or his mother he was aware of the presence of others. Questions were answered in monosyllables. The respiratory rhythm was more natural. There was a definite right facial paresis, the left angle of the mouth being drawn to one side when he spoke. He made such movements as he was asked to do. There was no rigidity and the pulse-rate was 1[illegible]4. He had a number of fits on March 9th in which the right side of the face and both arms were affected and the legs rigidly extended, and on the 10th he had five more at hourly intervals. On that day the latent period, which had been very pronounced in putting out his tongue, became much shorter. Both legs could be moved fairly well and equally, but there was a very noticeable tremulousness when he raised his right arm, as if the flexors and extensors of his elbow and wrist did not efficiently counterbalance one another. The right grasp was very weak. When the wounds were dressed the brain protrusion beneath the left flap was large, but that on the right was hardly perceptible. On March 13th the patient was bright and intelligent, and there had been no fits since March 10th. He was able to give his own account of his fall and of some of his preliminary symptoms. He also described the peculiar closure of the fingers of his right hand, already mentioned. The two grasps were now nearly equal, the facial paresis could barely be noticed when he smiled, the latent period and the leg reflexes were normal, and the swelling of the optic discs was subsiding. When the dressings were discontinued there was a rounded translucent swelling as big as half a moderate-sized orange over each decompressed area. These slowly increased and obviously contained cerebro-spinal fluid (see Fig. 1, left).

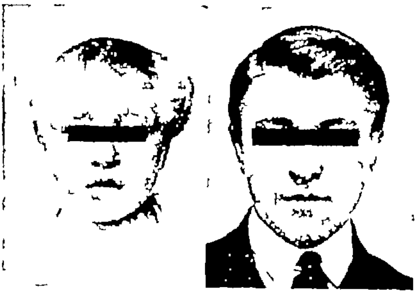

FIG. 1 (Case 1).—Left, in 191 , aged 10. Right, in 1919.

Further operations.—On May 14th, as the swellings tended to increase, an incision was made into the one on the left side. The brain still bulged through the gap in the bone ½–1 in. above the cranial surface. It was covered by a milky looking pia mater. The dura could not be distinguished, but the skin was lined on its deep surface by a distinct white membrane continuous at the margin of sac with the pia mater. The membrane was sufficiently thick for its edges at the incision to be sewn together before the skin was sutured. The tension of the right swelling was diminished by the operation, but only after paracentesis did the tumour disappear. Both swellings, however, soon re-formed and slowly increased.

On June 6th an incision was made behind the left ear and the sac opened. Its posterior wall was [illegible] and turned back upon itself and the [illegible] to the soft tissues beneath it. A piece of [illegible] foil was inserted into the sac and arranged [illegible] between the edges of the incision in the hope that it would prevent the opening from closing and allow the [illegible] fluid to drain into the tissues of the neck. The [illegible] was then closed.

Result.—From this date there was no further trouble and he was discharged on June [illegible] had healed. The translucent swellings gradually became smaller, but before they disappeared [illegible] as an out patient. They may have [illegible] months.

It was not till [illegible] not because of any [illegible] because he chanced [illegible] was then, to all appearances, a [illegible] young fellow. [illegible] either side [illegible] was a well-marked [illegible] plate lying over [illegible] the result of a number of bone chips which were placed under the flap before the original wound was closed The opening was by no means covered in 1919, but he has assured me that it is much smaller in 1936 and that the plate continues to grow It was in this year that I was able to get into communication with him He works at a clothing factory is married and has one child and does not remember feeling any ill effects from his accident during all the 21 years since the operation (Fig 1 right)

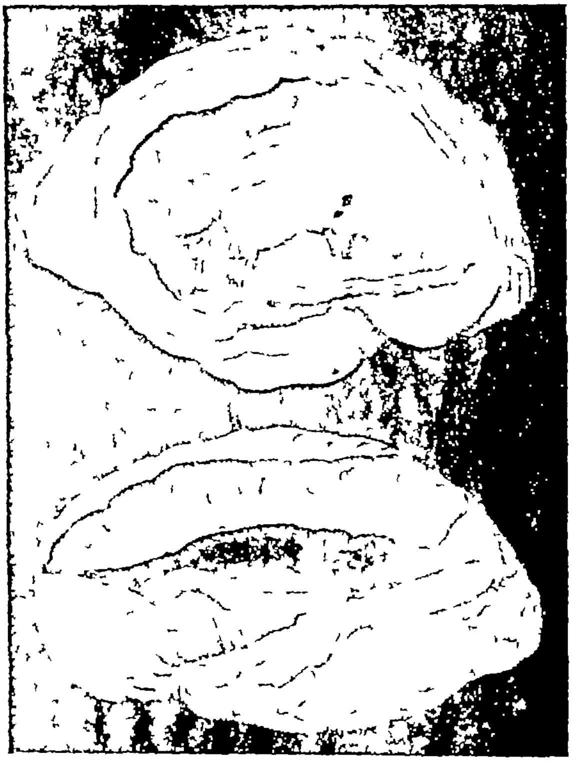

FIG 2 (Case 2) —Above the right cerebral hemisphere showing the lateral ventricle enormously dilated and the atrophic and fibrotic remains of the cerebral tissue Below the left lateral ventricle considerably dilated The pressure within it would be equal to that in the right ventricle The prolonged intraventricular pressure accounts for the degenerative changes in the left hemisphere described by Prof Jacob

(From drawings in *Brain* by R C Brown)

Comments—It was only after much thought that I came to the conclusion that the condition which had led to this remarkable combination of symptoms was almost certainly a diffuse non septic encephalitis involving at least one, or the greater part of one, of the cerebral hemispheres In making this diagnosis I was materially helped by the memory of another case which was fully recorded[1] in association with Dr R Cunyngham Brown It is unnecessary, and it would be tedious, to give a full account of that case, but some of its arresting features may be recalled, for they have a curious resemblance to those present in Case 1 and an important bearing upon their causation

CASE 2 —A boy aged 10 the son of healthy parents had had perfect health till 5 years before he was admitted into the Huddersfield Infirmary on Oct 3rd, 1891 under the care of my father His illness dated from a fall from a wall about 8 feet high and though apparently none the worse for the fall he was put to bed as a precaution The next morning he could not be roused and a doctor who was called in said he was suffering from "compression" He remained unconscious most of the day and then gradually recovered In a few days he was going about as usual A month later he had an epileptiform fit, and similar convulsive attacks occurred every other month for two years In the latter part of this period slight loss of power was noticed on his left side

He then had a second fall, this time from a height of only about 3 feet, and was taken up insensible For 2 weeks he lay unconscious and during that time he slowly emaciated, then he began to gain strength but was unable to get out of bed for 8 months Dr F L Mackenzie described him as having a purely vegetative existence at this stage For some time he lay in a state of "cerebral irritation," passing fæces and urine into the bed and becoming extremely emaciated Pulse rate 120, temperature 97 8° F, respirations regular Towards the end of this 8 months he began to improve, first moving about in bed and taking nourishment, but spastic paralysis of the left arm and leg slowly developed During this period the fits were in abeyance, but shortly after getting up he had one in which "he squinted and worked the left side" These attacks occurred 2 or 3 times a week and at first were controlled by treatment, but after 18 months treatment had no effect, and he would have 2 or 3 fits every day The loss of power increased, his behaviour became eccentric, and he was difficult to control For a fortnight before his death, which followed an exploratory operation he was under observation in the infirmary He had 3–4 epileptiform seizures every day, he was slow in answering questions, his enunciation was deliberate, and his behaviour abnormal, but his expression was intelligent

Histological report on corresponding portions of the right and left frontal lobes was as follows "Right considerably thinned, microscopically has lost all trace of nerve structure, showing no nerve-cells but merely condensed neuroglia infiltrated with inflammatory products Numerous inflammatory foci are present and the perivascular spaces are enlarged, pia mater shows marked inflammatory thickening Left the ordinary layers of the cortex can be recognised, but the nerve-cells show considerable degenerative changes and there is much dilatation of the perivascular spaces, there is no thickening of the pia mater" (Fig 2)

DISCUSSION

The features common to both cases are the remarkable attacks of compression and the atypical character of the symptoms The changes in the brain of Case 2 are sufficiently attested by the illustrations and by the microscopical report of Prof. E H Jacob of the Leeds University

The most remarkable point, however, is the fulminating type of the signs of compression in both patients immediately after injuries that seemed quite inadequate to account for them Though the question of initial concussion is not of very real moment in determining the conditions causing the compression, still the facts connected with its possibility may be considered

There is no record of any external injury in either patient and certainly none was present in Case 1 In that case, too, the diagnosis of compression was made within 30 min of the fall, so the concussion factor, if present at all, was speedily succeeded by signs of pressure But more impressive still was the triviality of the blow on the nose, and the way in which the lad fell on the ground This was quite inadequate to explain the rapid onset of such grave symptoms as to threaten death within 3 hours In Case 2 concussion, after the first fall, can be ruled out altogether or allowed to be only very slight, and yet the accident here was such that a severe injury might have occurred On the other hand, after his second fall it was quite possible that concussion might have deepened into compression, though as far as could be judged the injury was trivial, and quite nadequate to produce the severe cerebral mischief hat followed.

---

[1] *Brain* 1893 p 213

It has already been indicated that the symptoms n these two cases are atypical Those who are amiliar with the grave results of head injuries met ith in hospital wards will recognise that in spite of ome superficial resemblance the clinical picture resented by both is very different from that of extra ural hæmorrhage. Moreover the compression that ollows on concussion resulting from brain laceration n a case of severe head injury or fractured base can arely be in doubt while the history and the signs f external injury cannot be overlooked Again he practitioner could hardly confuse the common orms of cerebral hæmorrhage with either case; hilst the clinical course of intracranial tumours omes into quite a different category

Yet the two cases have an impressive likeness to ne another After a period of 36 years during which had come into close contact with innumerable cases f grave head injury the memory of the details of the arlier case remained clearly cut in my memory so learly that at once I was able to recognise how losely Case 1 resembled it. The clinical course of llness in Case 2 was undoubtedly the expression f a diffuse inflammation of the whole right hemi phere and of the deformation of both resulting rom the inflammatory softening and from the increased pressure of the cerebro-spinal fluid and the added inflammatory exudation above the iter It was not open to question that the encephalitis was acute, and not of septic origin and it was because of the certainty of the diagnosis in Case 2 that I ventured to make a similar diagnosis in Case 1

But the cause of the encephalitis is problematical. In Case 1 there is a definite possibility of infection for there is the story of the influenza followed by a series of prodromal symptoms till the sudden flare-up of the cerebral mischief was precipitated by an apparently trivial injury There can be no real doubt that the brain trouble arose from an infection and I regret that, though at the time I did not suspect it in the preoccupation of the moment I took no steps to ascertain its possibility In Case 2 the possibility of infection was never thought of. Bacteriology was then in its infancy and influenza had attained neither the virulence nor the fashion of modern times. Therefore, though the lad was stated to have had perfect health before his first fall it is quite likely that his friends, when they gave his *history dating back for 5 years* overlooked or did not realise that some childish ailment might have determined the gravity of the illness

I am much indebted to Mr P R. Allison surgical tutor to the Leeds General Infirmary for his kind help

Newton Abbot Devon

AN OMNIBUS SERVICE FOR A HOSPITAL.—Four doctors a hundred nurses, and nearly a thousand patients are petitioning the London Transport Board to provide an omnibus service to Hillingdon County Hospital At present out patients have to walk at least a mile each way

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—A beautiful house Burcot Grange Blackwell on the slopes of the Lickey Hills, has been presented to this hospital, and on March 12th it was opened by the Lord Mayor as the new annexe It will be staffed by a matron a sister and five nurses. Accommodation is provided for 1? women and 20 children

HYPOGLYCÆMIC SHOCK IN THE TREATMENT OF SCHIZOPHRENIA

INTERIM REPORT ON CASES TREATED AT ST BERNARD'S (FORMERLY HANWELL) HOSPITAL FOR MENTAL AND NERVOUS DISEASES

BY LEONARD W RUSSELL, M.B Ch B Leeds D.P.M
ASSISTANT MEDICAL OFFICER AT ST BERNARD'S HOSPITAL

AFTER the publication of Dr Isobel Wilson's[1] admirable study of the hypoglycæmic shock treatment in schizophrenia evolved by Dr M. Sakel of Vienna, I began to use this method at St Bernard's Hospital The method reported by Dr Wilson was closely followed so only a brief account will be given here Insulin is given intra muscularly to the fasting patient at 7 30 A.M. Dosage increases daily until the dose producing coma is reached in theory this is repeated daily throughout treatment but to obtain the desired 2–2¼ hours of coma daily, variations are needed Ordinarily coma is terminated by giving 10 oz of a glucose solution containing 7 oz of glucose by means of a nasal tube. Dangerous conditions calling for immediate termination of coma may arise epileptiform convulsions and laryngeal spasm both giving rise to cyanosis and collapse, are the most serious These alarming states are rapidly remedied by injection of 1 c cm. of adrenaline and further danger is averted by giving glucose intravenously or by nasal tube Return of the symptoms of hypo glycæmia may occur some hours after the usual termination (after-shock) this is treated as above, by adrenaline and glucose

The physical effects of large doses of insulin include shivering, pallor, nausea sweating salivation, myo clonus spasms of muscles convulsions and coma Here the pulse-rate has usually risen as shock con tinued, bradycardia being rarely seen (agreeing with reports from Munsingen and disagreeing with those from Vienna) The blood pressure has varied inconstantly seeming to depend on the restlessness or otherwise during coma The blood-sugar has shown a lowest value about three hours after injection not apparently related to the depth of coma.

Psychological effects are quietness lethargy sleep and coma. In the quiet period there may be lucidity After coma there may be a quiet, lucid period which when recovery is proceeding extends more and more into the conscious life of the patient Some patients wake very noisily with restlessness; the differing reactions resemble those of ordinary people waking after an anæsthetic. Affective response is improved early and the friendly spirit among patients undergoing treatment is remarkable.

Reactivation of the psychosis during the lighter stages of hypoglycæmia really does seem to occur (Dr Wilson disagrees) unexpected material from earlier stages of the psychosis is brought to light often seeming incoherent and futile until checked with the relatives

Cases were taken rather haphazard with a view to testing the treatment the old feeble and hopelessly demented were avoided

CASE REPORTS

CASE 1—Female aged 29 Nervous breakdown 11 years ago delusions of persecution 5 years, mental hospital 2 years Before treatment she was inter fering complaining pestering ; delusions of poisoning and *interference at night* related with winsome smiles Treatment commenced Oct 26th 1936 with 20 units of insulin Some insight shown on third day—"I must have been mistaken about those injections (of gas on into the gums at night) perhaps it was that the gums were sore" *Severe spasms and tongue biting* throughout treatment On the twelfth day had an epileptiform fit 3½ hours after 100 units of insulin Delusions soon became less apparent and her frequent complaining letters ceased Menstruated for the first time in 4 months *Treatment was stopped on the 71st* day on account of an influenza cold She was not satisfactorily comatose below 240 units of insulin and 290 units was the highest dose

---

[1] Wilson I G H (1936) Study of the Hypoglycæmic Shock

Result—Mental state is improved she feels that her delusions are being absorbed and she can laugh at them now Works in the ward is more serious in manner and affect is more congruous

CASE 2—Female aged 31 Similar attack 7 years ago Admitted 1½ years ago after a month of psychosis Had improved a little before treatment but was still impulsive, *verbigerant* staring vacantly and at times tearful for no good reason Treatment began Oct 26th, 1936 with 20 units insulin By the 5th day she was generally rational On the 10th day woke up and said "Everything has changed I seem to have come round" Afterwards she showed psychosis only during hypoglycæmia Dosage reduced from the 19th day and treatment ended on the 24th day she showed no psychosis for the last three days Coma dose of insulin was 80 units

Result—Mental state seems normal and she has been discharged over three months

CASE 3—Female aged 21 Admitted March 3rd, 1936, soon after onset Before treatment was in refractory ward resistive impulsive, usually *mute often stuporose* Treatment started Nov 9th 1936 Talked reasonably after hypoglycæmia on the first day Was soon garrulous and showed many bizarre delusions "I used to be a dead soul now I am alive and can breathe and laugh and feel my heart beating" On the 5th day four hours after 80 units of insulin had difficulty in breathing which passed off after insertion of nasal tube She did not respond to the usual glucose feed and became cyanosed, with pulse 146 and opisthotonos Intravenous glucose, *adrenaline and Coramine were given* she became restless, turning somersaults after more glucose at 3 15 P.M she settled down and gave no further anxiety Coma dose was 80 units of insulin and a maximum of 110 units was given treatment ending on the 39th day

Result—Mental state much improved and has further improved in the last months, she stayed in hospital on account of adverse home circumstances She still has unusual religious ideas—she was brought up in a convent—but works hard is pleasant and was discharged "on trial" on March 1st, 1937

CASE 4—Female aged 23 Admitted three years ago after a year of psychosis Before treatment was in a single room in refractory ward impulsive resistive babbling loudly and incoherently Incontinent and hand fed showing little affect of any kind Treatment began Nov 12th, 1936 with 40 units of insulin By the 7th day she was giving rational answers amenable and feeding herself On the 9th day *after coma following 80 units of* insulin she did not awake in spite of emergency measures was drowsy all day and had after shock at 11 P.M Further adrenaline and intravenous glucose improved her general condition but she was drowsy *for the next two days*, having glucose feeds by nasal tube Treatment recommenced on the 12th day when similar events followed a dose of 70 units Her pulse rate was about 120 all day and in the evening her temperature rose to 104 2° F Gradual improvement in the next two days was followed by the appearance of a rash which looked like chicken pox—though there was no source found for the infection and no other cases developed—on the 15th day Six days fastigium was followed by recovery in three weeks She became pleasant, talked easily and rationally was no longer incontinent and was able to go home for Christmas On Dec 29th treatment was resumed (using another brand of insulin) She became worse and from the 6th to the 22nd day was as she had been before treatment Since then she has improved and has provided no more alarming incidents Treatment discontinued after 51 days, she then relapsed after a week and further treatment again brought improvement Treatment is still continuing

Result—Mental state is improved, she can maintain a rational conversation though a little retarded, is docile, clean in habits, shows appropriate affective response

Comment—This case is of interest since she has had previous intensive treatment by Somnifaine, in three courses the longest lasting 19 days in April June, and September, 1935 She showed much less improvement with this treatment, persisting in her incontinent habits This is mentioned because there is still some question whether the improvement seen in the hypoglycæmic shock treatment is due to the extra attention given to the patients, results after insulin on the same case having been so much better (though her relapse after somnifaine had been into rather a worse state than before) and extra attention during the two methods of treatment being roughly the same, it seems that the extra attention is *not wholly responsible for the improvement* under insulin treatment

CASE 5—Female aged 41 First attack 11 years ago, admitted here three years ago Before treatment mute, almost inaccessible, violent, smashing glass and attacking other patients, refractory ward Treatment began Dec 3rd, 1936, with 30 units of insulin She talked from the start and rationally after a week though resistive and noisy in light hypoglycæmia Pulse of fibrillation during light hypoglycæmia which often settled to a regular rhythm as coma deepened After 30 days was able to go out for the day with her sister Subsequently the psychosis showed more plainly early delusions recurring and violence being frequent She became emaciated and treatment was ended on the 53rd day

Result—She has since settled down and is putting on weight, *she is accessible gives reasonable replies*, is quiet She is retarded, says that she "does not understand", delusions are now seldom evident in her talk

CASE 6—Female aged 25 Admitted July 18th, 1936, after a short mental illness Before treatment restless, resistive, manneristic, grimacing, seldom speaking Treatment began Dec 29th with 30 units of insulin On the 2nd day she had a fit with tonic and clonic phases and slight cyanosis, but no other likeness to epilepsy, this lasted for 5 mins As this was only 50 mins after injection and she was in good condition hypoglycæmia was not *interrupted* She did *not* sleep at all and at 11 30 A.M complained rationally of a severe headache, after drinking glucose was again mute By the 7th day was talking well, showing a delusion that her husband was dead, this delusion had gone by the 9th day She then began to have *hysterical symptoms, small "fits" of shivering* in which she would curl up and roll gently to the floor Insulin was omitted for one day and the fits ceased after 10 grains of Medinal After gradual decrease of insulin dosage treatment was stopped on the 18th day On the 20th day *she went out with her husband and her parents*, on the 23rd day she talked reasonably about her illness and, without prompting discussed marital difficulties (dyspareunia) During the night she relapsed, though next day had still insight and was distressed to feel herself again going into psychosis She became *noisy* hallucinated deluded, violent obscene and manneristic Further treatment brought back her lucidity 30 days after relapse was well behaved and rational Discharged "on trial" a week later (March 1st) and is still well and happy at home 48 days' treatment

Result—Full remission

CASE 7—Female aged 26 Admitted April 7th 1933, certified two years before *Before treatment resistive*, mute stuporose faulty in habits, hand fed A blood pressure of 80/64 mm Hg had rendered somnifaine narcosis abortive in 1935 Treatment commenced Dec 17th 1936 with 30 units of insulin On the 2nd day smiled reasonably, talked for the first time *in three years* but would not converse Blood pressure rose during hypoglycæmia to 100/75 mm Hg falling after termination this was inconstant On the 7th day had aftershock at 12 55 A.M easily remedied On the 8th day, after 110 units of insulin she did not wake as usual and was sleepy all day treatment was omitted for two days and glucose feeds given After 16 days of treatment she was in poor general health and treatment was discontinued A week later she developed a mild form of erysipelas her mental state was unchanged but recently she has shown more interest and now maintains a conversation attends occupational therapy classes is pleasant There is almost full remission but this may be due to the intercurrent erysipelas.

CASE 8 —Female aged 27 Admitted April 26th 1934 after six months psychosis Before treatment fatuous overactive mischievous manneristic, interfering destructive Treatment commenced Dec 30th 1936 On the 5th day she was giving sensible replies quieter She improved steadily until the 19th day when treatment was stopped for a week on account of bronchitis at the end of this week she was as fatuous as before After further treatment since Feb 2nd 1937 she shows a little improvement Affect is congruous she sits quietly instead of wandering about is more accessible and helps in the ward Lately during light hypoglycæmia she has shown a noisy phase of her psychosis. She had 69 days of treatment

SUMMARY

A report is given of 8 schizophrenics 5 having a longer psychosis than 1½ years treated by hypoglycæmic shock. All showed some improvement 2 with full remission 3 being much improved and 3 a little improved There were 416 periods of hypoglycæmia in all with only three seriously alarming incidents and 2 cases of "after-shock there were no lasting untoward physical results In general, the findings of the continental investigators (as reported by Dr Wilson) are confirmed the results being less impressive, probably on account of the more chronic cases treated.

I am indebted to Dr J B S Lewis medical superintendent of Hanwell Mental Hospital for permission to publish this report and for his advice in determining the diagnosis of cases for treatment

SCIATIC SCOLIOSIS

BY E N WARDLE M.Ch Orth. Liverp
F R C S Eng
ORTHOPÆDIC SURGEON TO THE BIRKENHEAD AND THE BOOTLE GENERAL HOSPITALS

SCIATIC scoliosis is a well known clinical entity which has not yet been placed on a satisfactory pathological basis We are all familiar with the gross variety of the syndrome, the patient with pain down one leg his whole trunk deviated to one side and the bent knee, but in the course of these observations attention will be drawn to another class of case which at present is I think, often labelled sciatica and left at that Even granted that sciatica is generally recognised now as a symptom and not as a pathological condition in itself the word is still too loosely applied. In fact, while collecting and observing this series of cases two things have impressed themselves. First the dramatic relief of pain obtained in some instances merely by placing the patient in the position of head suspension; secondly that the differential diagnosis of so called sciatica is a most important one and that more care is necessary in defining the condition referred to when the term is used

CLINICAL FINDINGS

A series of 26 cases is presented and, as the Table shows they have been divided into two broad types those with sciatic pain and an obvious scoliosis and those with sciatic pain in whom a slight degree of lateral deviation of the spine became apparent during examination The series was divided as follows:—

Total cases	26	Aged 25 or over	22
Male	16	Contralateral in Type I (per cent)	62
Female	10	Contralateral in Type II (per cent)	60

Type I cases—It will be seen that 16 cases fall into the first class, and I think this is the variety of case which has most often been described hitherto These patients always stand with the knee of the painful leg bent and the spinal deformity is obvious but it is a ' list rather than a true scoliosis Of this group 10 had a contralateral deformity that is to say the list of the spine was to the opposite side compared with the pain in the leg and 6 had deformity and pain on the same side.

The sciatic pain itself is of great interest because some patients have pain only a sciatic neuralgia, whereas many of them have a true sciatic neuritis which has been shown in this series by disturbed knee- and ankle-jerks in combination with one or more of the following signs stated in their order of relative frequency tenderness over the course of the nerve paræsthesiæ in the leg and foot and wasting of muscles Pitkin and Pheasant (1936) say that objective manifestations do not occur but their statement is not true of my cases Another unusual point about the pain is that it is referred to the course of the nerve and not to the area of distribution.

TYPE I CASES WITH OBVIOUS DEFORMITY

Case.	Age and sex.		Site of first pain noticed.	Onset of sciatic pain.	Deformity
1	M	30	Back	Rt few wks. later	Homolateral.
	M	30	Rt. leg	—	Contralateral
3	M	26		—	
4	F	15	Lt leg	—	
5	M	60	Back.	Rt few wks. later	
6	F	30		Lt., 2 wks. later	Homolateral
7	M	22	Rt leg	—	Contralateral
8	M	62		—	Homolateral
9	M	32	Back.	Lt 6 wks. later	Contralateral.
10	M	37		Lt., 9 mths. later	
11	M	38	Buttocks.	Rt mths later	Homolateral
12	M	29	Back.	Lt 2 yrs. later	"
13	M	39	Rt. buttock	—	
14	M	47	Back.	Lt 1 yr later	Contralateral.
15	F	22		Lt. wks later	
16	F	23		Rt., mths. later	

TYPE II CASES WITHOUT OBVIOUS DEFORMITY

Case.	Age and sex.		Site of first pain noticed.	Onset of sciatic pain.	Deformity
1	F	37	Rt. leg	—	Contralateral
2	M	32	Back.	Rt. 1½ yrs later	Homolateral.
3	M	40		Rt 10 wks. later	Contralateral
4	F	30	Lt. leg	—	Homolateral
5	F	25	Back.	Rt. 1 yr later	Contralateral.
6	F	23		Lt. few wks later	Homolateral
7	F	41		Lt some mths. later	Contralateral
8	M	37		Lt. 1½ yrs later	
9	M	55	"	Rt., 3 yrs. later	"
10	F	26		Lt. and rt., mths. later	Homolateral at present.

No patient has had complete limitation of movement of the lumbar spine The ranges most often curtailed have been found to be forward flexion and rotation to one side generally towards the side free from pain sometimes unilateral limitation of side bending has been associated with limitation of rotation and the limitation occurs in those directions which would stretch the painful sciatic nerve It has been common to find three out of the possible six directions of movement free This is in opposition to Putti's (1927) explanation that sciatic scoliosis is due to an arthritis of the small joints of the lumbar column such an arthritis should surely produce limitation of movement in all directions Muscle spasm is noticeable as a rule, but is on one side only

Type II cases—Out of the 26 in the series 10 patients have been placed in a separate class on account of certain well marked differences in their clinical aspect First of all sciatic pain was the outstanding feature, and they did not complain of deformity, as Type I cases do Although not noticeably scoliotic, nevertheless they were found to have slight lateral deviation in the lower part of the lumbar spine Radiograms showed a congenital malformation—e g sacralisation, spina bifida occulta, &c —to be present While quite satisfied that they could legitimately be included on clinical grounds, I became still more impressed by the fact that they were cured by the same treatment as the Type I cases with gross deformity These patients do not stand with the knee of the painful leg bent, and their deformity is slight enough to escape notice Their range of movements is limited in the same manner as the Type I cases and their pain is more often a neuralgia than a true neuritis

TREATMENT

Many methods of dealing with this most painful and intractable condition have been advocated They include rest, diathermy, massage and physiotherapy generally, injection of the painful sciatic nerve with novocain simple fixation in a plaster bed or cast manipulation of the spine under a general anæsthetic, and the application of a plaster jacket with the patient in the position of head suspension The last mentioned method is the only one, in my experience in which a relapse has not followed the apparent cure of the patient It is notable that it produces equally good results with patients of either type

A plaster jacket is applied with the patient in head suspension by means of a halter which grips the patient s chin and occiput and is attached to a block and tackle The patient is lifted until he signals that his pain has disappeared or alternatively, to the position where it is least Many patients obtained immediate and dramatic relief of the pain in this position but it has been noticeable that this does not occur in all cases in some the pain takes two or three days to disappear In patients with paræsthesiæ these disappear more slowly than the pain Even under full suspension some of the cases with very pronounced scoliosis did not straighten out completely but they have all been able to stand with straight legs whereas previously they had been forced to stand with one knee bent When incomplete correction occurs it is advisable to reapply a fresh plaster jacket by the same method after two or three weeks The jacket must be complete from the axilla to the trochanters and as soon as it has become hard the patient is lowered so that he is standing normally The necessary parts are cut out to allow walking sitting and moving the arms The plaster is applied over a stockinet vest with all the bony points well padded with felt

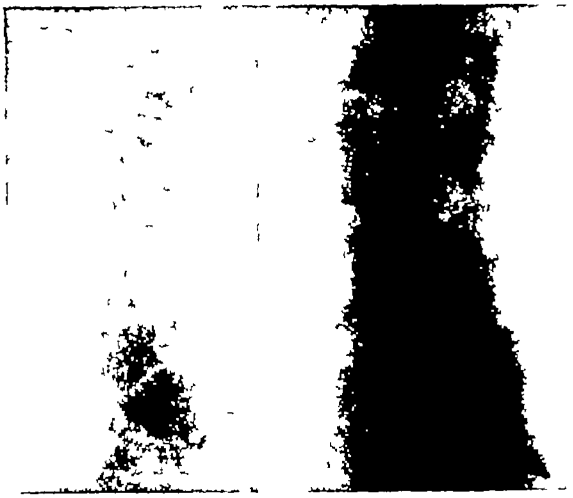
As a rule the jacket has been kept on for about eight weeks by the end of which period all the patients in this series have pronounced themselves free from pain The jacket is then split with the patient in head suspension again and a cast is rapidly made from the jacket after removal Before the patient stands again, the original plaster is reapplied and fixed with stropping and from the cast a lighter Pexaloid jacket is made of the same dimensions as the plaster When the pexaloid is finished and hard it is substituted for the plaster, and the patient continues to wear it for at least six months and sometimes longer

PROGNOSIS

All the cases considered obtained relief by this procedure—a large number of them immediately the head suspension was put into action, and the remainder within two or three days In all but three of the cases relief has been permanent up to the present, and these three cases are interesting enough to warrant a few detailed remarks

CASE 3 (Type I) —This patient was a very tall and heavy man he stood over 6 ft The deformity corrected almost completely in the first plaster, and the pain was relieved He took the plaster off because he did not like it, and the pain came back Another plaster was put on with the same effect, but when the pexaloid jacket was being made he left the plaster off again, and his pain came back The case was not proceeded with

CASE 2 (Type II) —This patient was quite a small man, but the history of his pain extended over more than two years His pain diminished very slowly Although he is going about his ordinary work now he states that his back aches occasionally



Left normal lumbosacral joint disc Right a narrow disc

CASE 5 (Type II) —This lady, after obtaining complete relief from a suspension jacket, had her pain recur after an interval of six months although the pexaloid jacket was worn continuously and she was very particular about carrying out all instructions After some consideration the lumbosacral region of the spine was grafted by the usual method four years ago, the graft extending from the third lumbar spine to the second sacral This patient reported as perfectly well in June, 1935, two years after the operation saying that she was quite recovered and that she was going abroad

In general, in those cases where head suspension produces dramatic relief of the pain, cure is certain, provided that fixation is continued long enough Where a *true* sciatic neuritis exists paræsthesiæ, in particular, often linger after pain has gone and clear up very slowly, and a more guarded prognosis must be given The benefit produced by treatment also depends upon the length of time for which symptoms have previously existed, where there is a long history relapse will occur easily with the slightest remission of fixation (for instance, shrinkage of the patient in the plaster jacket) during the first few weeks

RADIOGRAPHIC APPEARANCES

Williams and Yglesias (1933) suggested narrowing of the intervertebral disc at the lumbosacral joint as a cause of sciatic pain An examination of lateral X ray pictures of this series of cases suggested that this condition might be present in a large proportion

It is difficult to be accurate about the lumbosacral joint but it seemed worth while to examine the radiographs of the lumbar spine of as many apparently normal persons as possible By the courtesy of Dr P H Whitaker a hundred films taken for all sorts of purposes, were examined, and two things were noticeable first of all that narrowing of this joint space was a definite entity; and secondly that such narrowing never occurred in the first two decades of life

The Figure indicates the appearances which are referred to as a normal and a narrow lumbosacral joint disc. It is interesting to compare the ages of the patients there is only one patient out of the series whose age was less than 20 and the majority of the remainder were 30 or more

PATHOLOGY

It has been indicated earlier that the clinical findings in these patients oppose the theory that sciatic scoliosis is due to an arthritis of the lumbar intervertebral joints mainly on the grounds that a true arthritis should produce complete limitation of movement it is unlikely that the symptoms would always be unilateral if arthritis were present and that if such arthritic œdema were causing pain by compression of nerve-roots then it is extraordinary that the fourth and fifth lumbar roots appear to be the only ones ever affected There is further the occasional case of alternating scoliosis to be accounted for (Capener 1933) No true alternating cases were met with in this series, but there was one patient whose history suggested that his deformity had changed.

Much work has been done in recent years on the constitution and functions of the intervertebral disc and is associated with the name of Schmorl (1927); it is known that discs higher up the column atrophy and even herniate into vertebral bodies Taken in conjunction with the radiographic findings it seems possible that narrowing could easily occur at the lumbosacral junction The direction of the deformity may mean something in elucidating the cause of this condition for there are two possible explanations of the muscle spasm and deformity Irritation of the affected nerve-roots by pressure could produce muscle spasm reflexly on the same side of the body as the pain and in the second place an involuntary effort on the part of the patient to relieve pressure by opening up the neural foramen on the affected side would produce contraction of the muscles on the opposite side of the body to the pain—a contralateral deformity

SUMMARY

1 Cases of sciatic scoliosis have been divided into two types—those with and those without obvious deformity

2 Fixation in a head suspension plaster has produced relief of symptoms in 26 cases

3 It is suggested that the underlying cause of this condition is abnormal shrinkage of the intervertebral disc between the fifth lumbar and the first sacral segments of the spinal column.

In 1934 Soló described a "rapid culture method" for use in cases of suspected diphtheria Swabs were impregnated with serum and heated over a naked flame to produce surface coagulation of the serum They were used for swabbing throats in the usual way and incubated for two to four hours, a smear being then made from the incubated swab Soló claimed 80 per cent. of positive results in cases of diphtheria after two hours of incubation and a still higher percentage after four hours.

Brahdy Brody, Gaffney Lenarsky and Smith (1934) confirm this and state that they were able to give accurate reports in 95 per cent. of clinical cases of diphtheria within four hours using this treated swab, as compared with only 83 per cent accuracy in eighteen hours by the usual Löffler slope method and later (1935) they say that the technique is simple and the method quicker and more accurate than that using Löffler's serum medium. Parish (1935) in a letter and later (1936) confirms this, and states that the speed and reliability of diagnosis in diphtheria can be improved by the use of serum treated swabs

There is a general consensus of opinion that the direct smear is of little value in the diagnosis of diphtheria. Topley and Wilson (1936) state that as a method of confirming or refuting a clinical diagnosis of diphtheria this procedure has little to recommend it Gray and Stone (1936) examined 1000 swabs sent to their laboratory 202 were positive on culture 33 were positive on direct smear and of these 4 were negative on culture 2 of them showing no clinical evidence of infection They consider that these findings emphasise the need for caution in the interpretation of positive results in direct films but conclude that primary examination of direct films is useful in aiding the clinician in doubtful cases

We decided to compare the results given by the serum treated swab with those given by the ordinary direct smear and by culture on Löffler's medium

TECHNIQUE

Swabs taken by one of us from cases in Ladywell Isolation Hospital were examined independently by the other at the Salford City Laboratory on the same day No clinical information was supplied with the swabs sent to the laboratory

Serum treated swabs were prepared as follows —

Ordinary throat swabs were soaked in filtered ox serum and heated in the hot-air oven at 80° C for fifteen minutes This method as recommended by Parish (1935) was found more satisfactory than heating the swabs over the naked flame Direct smears from these and from ordinary swabs were prepared by moistening the swab with one or two drops of water and tapping it firmly on a slide The slide was left to dry at a slight angle so that a portion of the resulting film was fairly thick, thus facilitating the search for organisms when they were not numerous Cultures on Löffler slopes were incubated for 18 hours before examination All smears were stained by Pugh's method this being the stain used for routine work in the City Laboratory

RESULTS

Throat swabs were taken from 428 cases, which were classified as typical diphtheria clean throats, and doubtful cases (see Table)

Group A—In 228 cases three swabs of each throat were taken one serum treated which was incubated for four hours at 37° C before making a smear from it and two plain swabs, one of which was used to make a direct smear and the other was cultured on a Löffler slope

Group B—In 100 cases two swabs of each throat were taken one serum treated (further manipulation as in the first group) and one plain swab from which a direct smear was made after inoculating a Löffler slope

Group C—In a third group of 100 cases three swabs were again taken from each throat, but the serum treated swab and one plain swab were both incubated at 37° C for four hours before making smears and with the other plain swab a Löffler slope was inoculated

In every case the serum treated swab was taken first

Results from Different Methods

	Total No of cases	Positives—		
		Serum treated swab	Direct smear	Löffler
Group A—				
Typical throats	118	91	81	114
Clean	91	20	11	61
Doubtful	19	3	3	8
Group B—				
Typical	63	48	43	63
Clean	29	10	6	22
Doubtful	8	0	0	2
Group C—				
Typical	83	65	64	79
Clean	17	3	2	15

From the Table it will be seen that, considering only swabs from typical diphtheritic lesions, the serum treated swab was positive in 204 cases out of 264 that is 77 per cent The direct smear was positive in 69 per cent (of 118 cases) when a separate plain swab was used for this purpose, and in 68 per cent (of 63 cases) when the same swab was also used to inoculate the Löffler slope When the plain swab also was incubated for four hours, the direct smear was then positive in 77 per cent (of 83 cases), as high a percentage as that given by the serum treated swab Although the numbers are small they suggest that the improved results given by the serum treated swab are mainly due to the incubation that it received

Our percentage of positive results with the serum treated swab are lower than those obtained by the American workers quoted, and by Parish (77 per cent as against 95 per cent) This is probably due to the atypical appearance of the diphtheria bacilli in the smears from these swabs as many of the bacilli had lost their metachromatism and appeared as uniformly stained rods which could not with confidence be distinguished from diphtheroids Unless some of the commoner pleomorphic forms such as barred, club shaped, irregularly staining, or granular bacilli were also present, smears were reported as negative Due regard was also given to the arrangement of the bacilli in the smears "Chinese letter" formation being regarded as evidence in favour of the organisms being true diphtheria bacilli

The diphtheria bacilli on the whole were much more typical in the simple direct smear from the untreated swab and in cases of clinical diphtheria were usually found without any laborious search Here again smears were not considered positive unless fairly typical diphtheria bacilli were present in moderate numbers

The results obtained by culture on Löffler s medium are superior to those given by smears from the serum treated and ordinary swab In 264 cases of clinical diphtheria, 97 per cent were positive on Löffler, 77 per cent on the serum treated swab, and 71 per cent by the direct smear Our percentage of positive cultures on Löffler is higher than obtained by the workers quoted We think this may be due to careful preparation of the medium and storage so as to avoid drying In a previous preliminary note only 87 per cent of 82 cases of clinical diphtheria were reported positive on culture Since then overhauling of the preparation and storage of the medium on orthodox lines have resulted, we believe, in the better results now published

In clean throats—previously typical cases—98 of 137 (72 per cent) were positive on Löffler, and 33 of 137 (24 per cent) were positive with the serum treated swab These results show that culture on Löffler is much more satisfactory than the serum treated swab for the detection of carriers, or in examination of cases for discharge from hospital.

The numbers of clinically doubtful throats swabbed is small In 2 of 27, positive results were recorded by the serum treated swab and direct smear, where culture on Löffler was negative Of these two cases one patient had diphtheria previously and was Schick negative, and antiseptics had been applied to the fauces prior to swabbing, while the other was suffering from scarlet fever with powdery deposit on the tonsils, and four subsequent cultures were negative This suggests a high percentage of false positives in doubtful cases, which we think is misleading in view of what follows

All throat swabs sent from cases of suspected diphtheria by practitioners to the City Laboratory during laboratory hours are examined by direct smear after a culture has been made on a Löffler slope An analysis of the last 3000 throat swabs shows only 8 positive on direct smear which were not positive on culture In the same series, 302 swabs were positive on culture and the cases admitted to Ladywell, direct smears gave positive results in 40 per cent of these swabs This is a much lower percentage of direct smear positive than that obtained in our series of cases of typical diphtheria, and can probably be explained by three factors

(1) Special care was taken in swabbing the throats for this investigation It is often difficult to obtain a good swab from a refractory child, but it is much easier with hospital facilities which are not available to the general practitioner

(2) Of the cases reported positive on Löffler and admitted to Ladywell 25 per cent were not true clinical diphtheria

(3) Swabs from cases in the hospital were taken on an average a day or so later in the course of the disease than those taken from cases outside This may have resulted in a higher proportion of direct smear positives

It is interesting to note that in this same series of swabs sent from outside to the City Laboratory, 52 per cent of the cases admitted with clinical diphtheria were positive by direct smear as well as on Löffler, and no case positive on Löffler which was not clinically diphtheria was positive by direct smear

CONCLUSIONS

We do not recommend the serum treated swab as a routine method for the diagnosis of diphtheria Apart from the difficulties of distributing freshly made swabs to the general practitioner and dealing with them on return to the laboratory the results given by them show only slight superiority over those given by the simple direct smear

All swabs sent from suspected cases of diphtheria should be examined by direct smear after inoculating a Löffler slope or other suitable medium. We believe that about half of the swabs sent for examination from cases of diphtheria will be positive in direct smears made in this way

We wish to thank Dr Edge medical superintendent of the Ladywell Sanatorium and Isolation Hospital for permission to investigate the cases

Clinical and Laboratory Notes

CEPHALIC TETANUS

A CASE TREATED WITH INTRAMUSCULAR MAGNESIUM SULPHATE

By Paul B Wilkinson M.R C P Lond
MEDICAL OFFICER COLONIAL MEDICAL SERVICE, ST HELENA

This case seems to be worthy of record first because cephalic tetanus is a rare form of the disease and secondly because much interest has recently been roused by newly devised methods of treatment for tetanus. The case is also of interest because it shows how confusing the physical signs can be during the onset of the disease when progressive involvement of the cranial nerve nuclei is slowly occurring

CASE REPORT

The patient was an island boy aged 17 On Oct 5th while at work he had slipped on a rock and fallen head first down a small waterfall He landed on the left side of his head, but did not lose consciousness He was picked up by his fellow workers and brought to me at once

On examination two clean cut wounds 1¼ in. and ½ in long were found on the scalp over the left pterion and parietal eminence respectively Probing revealed no evidence of fracture of the skull and there had been no bleeding from mouth nose or ears The tympana and fundi were normal There was no evidence of lung or other injury The scalp surrounding the wounds was shaved, the wounds were cleaned with hot 1 in 1000 perchloride solution and 5 silk worm gut stitches were inserted.

Next day the wounds looked clean and he complained merely of aching in the left shoulder due to bruising The wounds were redressed

On Oct 9th the edges of the wound over the parietal eminence were puffy stitches were removed and a small amount of pus expressed smears showed staphylococci only As he stated that he had bled from the right nostril on the preceding afternoon he was admitted to hospital and the wounds were dressed thrice daily with eusol A fracture of the cribriform plate was feared and a temperature of 101 6 F on the night of admission lent colour to this since the condition of the wounds did not account for the degree of fever but on examination the nervous system was normal The boy continued to show a nocturnal rise of temperature to 100 F and on the morning of Oct 11th his left upper lid was drooping and he complained that he could not keep the eye open The pupils were central and equal reacting sluggishly to light; direct and consensual reactions were obtained No head retraction and no neck rigidity tendency to a positive Kernig on both sides, more on the left than on the right No other signs in the nervous or other systems Temperature normal pulse rate 84 He was perfectly rational and complained of nothing but the inability to open the left eye His condition did not appear to be that of incipient meningitis Cerebro spinal fluid clear and colourless; no increased globulin

During the next three days the nocturnal fever abated and his condition seemed to improve slightly The only new symptoms were attacks in which 'everything went black,' a transient amblyopia lasted 5–10 mins Unfortunately I never saw him in one of them He had in all five such attacks His fundi were still normal

Oct 15th The right upper lid drooped; the left eye could now open; left half of the face weak On looking to the right the left eye did not cross the midline No diplopia, and all his reflexes were normal and symmetrical plantar response flexor

Oct 17th He had a peculiar skew deviation of the eyes The right eye whose orbicularis palpebrarum was in spasm, was directed downwards and outwards when the lid was raised, and the left eye upwards and outwards The left eye had a full range of movement but the right did not cross the mid line on deviation to the left The fundi were normal. He now complained of stiffness in the left side of the face which was still weak. The left masseter was rigid on palpation. The right was normal. Tetanus was diagnosed and 150 000 units of anti tetanus serum were immediately given intravenously Six hours after the injection the boy showed well marked opisthotonus and trismus, and his speech had become typically tetanic. He had had two generalised spasms since noon He lay with the arms flexed at the elbows, but in neither arms nor legs was there much rigidity at this stage

Oct 18th: Opisthotonus more pronounced though the trismus and speech were better Downward deviation of the right eye disappeared The right eye now simply deviated out from the midline The right orbicularis was still in spasm and the left was partially paralysed He thus lay with the right eye firmly closed the left half open. He was not sweating perceptibly but was much troubled by salivation so excessive that he used a handkerchief continuously and it had to be controlled with atropine The pulse rate was 86 but the temperature was normal.

It was decided to try the effect of intravenous Evipan Sodium and gr 5 dissolved in 10 c.cm of distilled water were slowly injected into the right basilic vein When only 5 c cm of the solution had been injected he had a violent generalised spasm followed quickly by six others during which he became cyanosed Presumably this was because evipan exercises an almost immediate depressant influence on respiration and this, added to the fixation of the thorax, increased the tendency to convulsion He was still swallowing fairly well and was ordered chloral gr 20 sodium bromide gr 30 every two hours. Avertin not being available treatment with intramuscular magnesium sulphate was begun the same evening 10 c cm of a sterile 10 *per cent* solution were injected into the right vastus externus His rigidity gradually lessened and within 45 minutes of the injection it had become impossible to pass a hand under the back. Breathing became a little shallower and slightly irregular but his pulse remained good An hour later he had a generalised spasm, caused by turning a blanket back and 1¼ hours after the injection he began to have mild spasms again Since the doses had definitely produced some relaxation and procured him 1¼ hours of practically unbroken sleep it was decided to continue the injections 4 times a day These were given on Oct 18th–30th and altogether he had 86·65 grammes of magnesium sulphate Chloral and bromide were also given two hourly gr 40 and gr 60 increasing to gr 60 and gr 120 respectively but from the 23rd onwards it became impossible to give the mixture two hourly owing to the œsophageal spasm The dose had to be reduced and it was no longer possible to keep accurate records of the amount taken

Oct 19th: Condition materially unchanged; two generalised spasms during the day but no new signs limbs not yet affected A pint of glucose saline given per rectum night and morning

On Oct 20th and 21st his condition deterior pulse-rate rose to 100 and swallowing the puncture especially to leakage of cerebro spinal fluid through the puncture hole The use of as fine a needle as possible prevented neither leakage nor headache He advised inserting the needle in the midline by steady pressure, with the bevel in the long axis of the body, and the patient in the Trendelenburg position Imperfect technique produced gross damage to the nervous tissue, and he had seen two such cases after too high a puncture The needle should never be inserted above the third lumbar vertebra Failure to get into the proper space was due to inexperience When bleeding from injured vessels occurred he wondered if sequelæ could be due to a hæmatoma or to the later development of adhesions The effect of the drug should wear off immediately after operation The commonest trouble was interference with the emptying of the bladder, common after rectal operations with any anæsthetic He thought that the anæsthetic drug itself produced the symptoms, some of which for example the headache and rigors following Percaine might be due to faulty preparation of the anæsthetic solution Two of the commonly used solutions contained alcohol which added an unnecessary risk The concentration of the drug was extremely important, dilute solutions producing temporary and concentrated ones permanent paralyses He preferred larger quantities of lower concentration and suggested for greater safety the mixing of the anæsthetic solution with an equal quantity of cerebro spinal fluid before injection

SPINAL ANÆSTHETICS IN EXPERIMENTAL WORK

Prof A D **Macdonald** spoke as an experimentalist He would be the last to apply conclusions from dogs and cats directly to man, but the difficult problem of why spinal anæsthetics sometimes caused death on the table or were followed by bladder or rectal symptoms called for all possible help In the cat spinal anæsthesia could be easily produced His first endeavour had been to determine with his co workers the fate of the drug used They had investigated numbers of the procaine series (Larocaine, Tutocaine Planocaine) which coupled with guaiacol disulphonic acid give a brilliant colour suitable for colorimetric study They had proved that they were estimating the anæsthetic itself and not a degradation product In cats 0·5 c cm of a 10 per cent solution of procaine corresponding to a dose of 20–30 c cm in man could be safely injected The effect lasted 30-50 minutes knee jerks returning with a concentration in the lumbar fluid of 0·05 per cent Ten minutes after injection the concentration in the lumbar fluid was 2–3 per cent and in the cisterna magna 0·002 per cent, showing amazingly little spread headwards The concentration in the blood was low, the full spinal dose had been administered slowly intravenously in man without ill effect The acute effects of lumbar injection in the cat were increased movement of the diaphragm owing to the paralysis of the intercostal muscles and fall in blood pressure from 130 to 80 mm Hg Injection at the third cervical level produced diaphragmatic paralysis with increased thoracic movement and into the cisterna magna intercostal and diaphragmatic paralysis Blood pressure first rose falling with failure of the respiratory centre Artificial respiration prevented death

Sequelæ after 0·5 c cm of a 10 per cent solution were recognised in the experimental animal by tail droop bladder and rectal symptoms and weakness of the limbs No other constituent of the injected solution except the actual anæsthetic (Duracaine, Planocaine, Stovaine) produced sequelæ in cats The severity of the symptoms varied directly with the concentration of the drug Using 2½, 5, 10, and 20 per cent solutions, the incidence of paralysis was respectively 0 10, 43, and 80 per cent Two well established ideas should be considered in any explanation of these sequelæ Sherrington had said that a change in any part of the spinal cord was more likely to occur at the synapse than in the fibres, and Gasser had shown that the finest fibres were those most easily and permanently affected by local anæsthetics

SOME SUGGESTIONS

Dr **Fergus R Ferguson** said that post operative difficulties with micturition or defæcation were too often disregarded In Manchester many sequelæ had been seen and he had records of thirteen cases with the neurological picture of a cauda equina lesion seen between August, 1933, and March, 1935, after heavy duracaine anæsthesia Eleven were men and two women, and the age varied from 17 to 70 years The eight severe cases in the series followed emergency operations There was much variation in severity, the clinical features being absence of one or more leg tendon reflexes, retention of urine, incontinence of fæces, sensory loss over the third, fourth, and fifth sacral areas, and loss of sexual function It seemed that the roots nearest the injection were in the greatest danger Sequelæ, especially retention of urine and fæcal incontinence, though seemingly trivial at the time, could be devastating and lasting As to ætiological factors, he thought that concentration of the anæsthetic and duration of the contact were most important In the series recorded the site of the lesion was the cauda equina, though other syndromes were reported Trauma alone could not cause sequelæ, though it might play a part It seemed impossible for hæmorrhage to produce such widespread lesions, and there was no evidence of bleeding It was strange that after tens of thousands of diagnostic lumbar punctures there had been no sphincter nor reflex complications, and they did occur after a perfect anæsthetic puncture The variation in the severity of the symptoms seemed incompatible with trauma Post mortem and experimental evidence suggested a toxic effect No local cause could explain the frequent sixth nerve palsy Other constituents of the injected fluid had come under suspicion especially alcohol but 3 c cm of 90 per cent alcohol could be injected without sequelæ Since heavy duracaine had been introduced for its slow diffusion, the undiluted procaine might be held too long in contact with the nerves He concluded that duracaine was dangerous, and should not be used, and that for safety the procaine solution should be diluted with an equal quantity of cerebro spinal fluid, and given slowly

DISCUSSION

Dr **Russell Brain**, opening the discussion reported a case of myelomalacia in a man of 63 following Spinocaine beginning with pain in the lumbar region one week after operation Pain in the left knee followed with difficulty in walking, and numbness first in the left leg, then spreading to the waist Later there was retention of urine and finally death from intercurrent infection The time intervals in the progress of the case suggested a possible sensitivity to foreign protein

Dr **Dorothy Russell** gave an account of the changes in the central nervous system in this case The main lesion was a softening of the spinal cord between the twelfth thoracic and second lumbar levels with necrosis of the whole substance of the cord complete in the grey partial in the white matter. Microscopic study showed thrombosis and necrosis of the walls of the pial arteries. She considered that the primary effect was on the vessels with secondary necrosis of the grey matter. There was no evidence of direct trauma, nor of old hæmorrhage nor was there anything to suggest infection introduced by the needle.

Dr H K **Ashworth** said that the sequelæ could be divided into those dangerous to the patient and those that were transient. Of the first he mentioned the cauda equina lesion described by Dr Ferguson and the precipitation into activity of incipient disease of the nervous system. He blamed the concentration of the anæsthetic and its combination with other injected substances at the site of the injection. The chief transient sequela was a sixth nerve palsy of which he had seen two examples in a total of some thousand percaine anæsthetics. Though one had lasted for four months both had cleared entirely. More serious as far as the dissatisfaction of the patient with the anæsthetist was concerned was headache due to alteration in cerebro spinal fluid pressure. In a recent series in the German literature it had been shown that the incidence of headache was higher in the younger than in the older patients but was unrelated to the size of the lumbar puncture needle. Its occurrence even after preliminary Evipan suggested that the functional element was small.

Dr **Wilfred Harris** could not believe that the sequelæ were the direct effect of the action of concentrated anæsthetic on the nerves. He had a large experience of the injection of cases of sciatica with 2 per cent and 5 per cent Novocain and in no case was there ever more than a transient anæsthesia or paræsthesia in the sciatic distribution. He regarded the lesion as sacromyelitic, and thought that the myelitis might be due to a vasoconstrictor effect of the procaine.

The **President** referred to a case described by Langton Hewer where percaine had been used and quoted two cases of temporary mania following that drug recorded by Dickson Wright. He asked what was the effect of the anæsthetic on the spinal blood vessels.

Prof. **Macdonald** asserted that straight percaine and novocain had no effect on the blood vessels. He and his students had given frequent injections into the skin of the procaine series and had found that in the absence of adrenaline there was if anything vasodilatation. The solutions were 10 per cent and stronger than those used by Dr Harris.

Dr **Russell** referred to unpublished work that demonstrated fibrinoid necrosis in the renal vessels of the rat following injection of pituitary extract.

Dr **Ferguson** said that he had not necessarily assumed a direct action of the anæsthetic on the cauda equina in the cases with the clinical syndrome of a cauda equina lesion. He had not had time to describe post mortem appearances in three of his cases. There was evidence of vascular disease an increase of hyaline material in the vessels walls and decrease in the size of the lumen in the posterior root ganglia in the lumbosacral region.

Dr **Purdon Martin** referred briefly to a case of ascending myelitis progressing to encephalomyelitis following spinal anæsthesia. Unfortunately he had not seen the pathological material.

Dr **Critchley** emphasised that the object of the meeting was not in any way to disparage a method that had proved itself useful, if not invaluable in medicine but rather to promote discussion to try to prevent the unpleasant and sometimes disastrous sequelæ.

LIVERPOOL MEDICAL INSTITUTION WITH MANCHESTER MEDICAL SOCIETY

A joint meeting was held at Liverpool on March 4th with Prof R E **Kelly** in the chair.

Mr R L **Holt** read a paper on

Gastritis

in which he stated that for the past eighteen months he had been collecting fresh specimens of stomach following partial gastrectomy for chronic gastric ulcer. His histological findings were substantially the same as those described by Konjetzny Kalima Puhl and others. They differed simply in degree a change readily explainable by the difference between pre-operative treatment in this country and in continental clinics. In more than half his cases there was naked-eye evidence of a subacute gastritis which was most marked in the pyloric antrum but extended to a lesser degree into the duodenum and body of the stomach. On microscopical examination all his specimens showed evidence of a subacute or chronic gastritis. The histological changes were distributed in a patchy fashion throughout the gastric mucosa, erosions alternating with areas of normal mucosa hypertrophy and atrophy. He suggested that in this country we were apt to stress the importance of the presence of a definite peptic ulcer and to neglect the larger number of cases which had all signs and symptoms of peptic ulceration except X ray evidence of an ulcer. There was no doubt that the signs and symptoms usually associated with chronic peptic ulcer could be reproduced by a pyloric gastritis according to Faber the signs and symptoms were produced by the gastritis and not by the ulcer. Mr Holt went on to consider the factors generally considered of importance in the genesis of chronic gastric ulcer and said in his view chronic ulcer might well be considered as a complication occurring in a case of pyloric gastritis. Most patients who consulted their doctors on account of gastro intestinal disturbances were still classified non-committally as dyspepsia of one sort or another. He hoped that the recognition of the frequent occurrence of gastritis and the signs and symptoms which it produced would prove to be a great step forward in penetrating this diagnostic fog.

In the discussion which followed, Prof. **Henry Cohen** referring to the president's question What is indigestion? feared that if certain current continental ideas on gastritis were accepted the impetuous surgeon would not stay *for an* answer but would proceed to partial gastrectomy. Such mutilation was in his view quite unjustifiable in our present knowledge of the subject. We had yet to define with much greater care the condition of chronic hypertrophic gastritis the factors which played a part in its production and its relationship to gastric ulceration. It had been stated that gastritis almost invariably precedes ulceration and cancer of the stomach but Church, Walters and Wellbrock of the Mayo Clinic had shown that pyloric obstruction itself was a very important factor in producing gastritis which was practically absent in cases of carcinoma of the stomach without pyloric obstruction but was present in eleven out of twelve cases with pyloric obstruction. Many exogenous factors could cause inflammatory changes in the gastric mucosa—mechanical, chemical, thermal and bacterial The president had referred to the observations of Beaumont on Alexis St Martin, Prof Cohen recalled that after St Martin had been drinking "ardent spirits" for nearly a fortnight, Beaumont found characteristic changes of gastritis including erosions Atrophic gastritis with achlorhydria had been studied in much greater detail Its association with hyper and hypochromic anæmias, subacute combined degeneration of the spinal cord certain types of polyneuritis and steatorrhœa had been firmly established

Mr J Howell Hughes said that gastroscopy had revealed three types of gastritis (*a*) the catarrhal, which showed change of colour of the mucous membrane from the normal orange to a deep red colour often with submucous hæmorrhages, (*b*) the atrophic, pale flat mucous membrane usually seen in anæmias, and (*c*) the hypertropic type Mr Holt had discussed the pathological changes in the last, but similar changes were seen by means of gastroscopy tortuous and redundant rugæ small granulations on the rugæ, sometimes small varicosities and in some cases small acute erosions In this type a certain rigidity of the mucous membrane was obtained so that rugæ which normally flattened with air distension were still present and therefore it seemed as if a permanent change in the mucous membrane had taken place

Mr John Morley said that while it had been certainly proved that gastritis could be found in the mucosa surrounding gastric and duodenal ulcers in a large proportion of cases we had hardly evidence to prove whether this condition was a predisposing cause or a result of the ulceration Where pyloric gastritis was present without gross ulceration it was impossible to detect it without opening the stomach (apart from previous gastroscopy), and he felt some misgivings lest if ever such an intangible lesion came to be regarded as an indication for partial gastrectomy, that very valuable operation might fall into disrepute With regard to the atrophic gastritis associated with achlorhydria the difficulty was that the condition was very common, and increasingly so with advancing age and as a rule gave rise to no dyspeptic symptoms The claim sometimes made that atrophic gastritis was a common predisposing cause of cancer he regarded as entirely unproved

Dr L Savatard read a paper illustrated by lantern slides on

Tumours of the Skin

in which he stressed the clinical and histological evolution of the epithelioma in its progress to metastasis The diagnosis of the early epithelioma was thoroughly portrayed and the multiformity, clinically and histologically, of cutaneous cancer was demonstrated

---

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY

At a meeting of this society held at Liverpool on Feb 26th with Dr J W Bride the president, in the chair a case of

Mucocele of the Appendix

was shown by Mr J W Burns

The patient was a female, aged 42 who had found a lump in her side She had had four full time normal labours the last one 9 years previously Menstruation had been normal Her only symptom was a "stretched" feeling in the right side relieved by loosening her clothing There was no history of indigestion, vomiting, or pain On examination a sausage shaped tumour could be felt in her right iliac fossa It was not absolutely fixed and there was no tenderness or rigidity Per vaginam her pelvic organs appeared normal and the lower pole of the tumour could just be reached at the brim of the pelvis An X ray investigation of the alimentary tract was made which showed that the cæcum was displaced towards the midline by the tumour In consultation it was agreed that a laparotomy should be performed The tumour was found on the outer side of the cæcum from which it had become sealed off but it had become attached to the parietal peritoneum on the posterior wall by its distal end The tumour was removed and found to be filled with translucent fluid Its size was 7 by 3 by 2 in

Mr Burns said that great care was taken to avoid rupturing the cyst In his opinion if this had taken place a condition of pseudomyxoma peritonei would have arisen with the appendix as the original focus

The President said that a mucocele of this size must be very uncommon He wondered what the connexion between pseudomyxoma peritonei and mucocele of the appendix really was

Full-term Extra uterine Pregnancy

Dr F J Burke showed two cases with extra uterine pregnancies that had gone to term In each a macerated fœtus was found at laparotomy From one a degenerated placenta was removed without bleeding, but the patient died an hour later from hæmorrhage into the gestation sac In the second the placenta was attached to the uterus only by a thin pedicle and it was easily removed, the patient recovering

Prof Miles Phillips said that in his experience the management of the placenta was the important point at operation He thought it best to leave it alone He had had 6 cases, 1 of which he opened again some years later for another condition Nothing was found in the abdomen except a few adhesions —Dr Robert Newton inquired whether it would be an advantage if the fœtus were dead to leave the case alone for some time —Mr St George Wilson showed a photograph taken post mortem of a woman aged 80 who had died of a broken femur In the abdomen was a large calcified fœtus —Dr J H Willett said that he thought it very bad practice indeed to start exploring the abdomen too freely owing to the risk of serious hæmorrhage from separation of the placenta He thought the operation should be done at once when the fœtal heart had ceased —Prof W Fletcher Shaw mentioned the case of his own in which a living fœtus had been removed

Dr Burke, in reply, said that he thought his first case would have died of septicæmia if she had not been operated on In both his cases a diagnostic difficulty had been that no fœtal limbs could be felt

Locked Twins

Dr W S Wright showed a case of locked twins in a primigravida aged 21 The first fœtus delivered had to be decapitated to free the second, which was in a state of white asphyxia when born and did not live The *mother recovered*

Dr Wright said that von Braun had estimated the frequency of locking as 1 in 90,000 He said there were four ways in which locking might occur (1) Both fœtuses presenting by the vertex entered the pelvis side by side (2) As in his case, the first child presenting by the breech, the second by the vertex the heads become locked by the chins (3) The first child, presenting by the breech may become locked by the chin on the body of the second fœtus lying transversely (4) Both fœtuses presenting by the foot may enter the pelvis together

Prof. PHILLIPS said that he thought a deficiency of liquor amnii was a possible cause —Dr C M. MARSHALL said that for purposes of decapitation a saw could be passed round the fœtal neck with the thumb and forefinger using a Blond Heidlar thimble

Varicocele in the Female

Prof. FLETCHER SHAW said that while all text-books mentioned the condition none gave a satisfactory account of it He quoted Emge who had said that the condition was the result of damage to the fibro elastic suspensorium and that only a small portion was the result of lesions in the walls of the vein. Carlos Castano had stated that it was the disease with the most subjective and the fewest objective symptoms. Graves had pointed out that the condition was often mistaken for inflammatory adnexal disease. Prof Fletcher Shaw said his attention was first drawn to the subject by the late W E Fothergill in 1921 He said he was rather sceptical of a condition which could only be recognised in the erect position Shortly afterwards his doubts were rudely shaken as in 1923 he had three cases in one month the notes of which he read to the society They were aged 26 35 and 31 and complained respectively of dysmenorrhœa menorrhagia, and backache, of recurrent acute abdominal pains and of aching pain in both iliac regions They were diagnosed as chronic salpingitis or matted appendages and were treated by ligation and excision In one case the condition recurred on the opposite side and required pan hysterectomy The other two were cured Prof Fletcher Shaw said that some thought retroflexion a probable cause of this condition but only one of the three had a retroflexed uterus He said that pressure on the broad ligament on the left side by the sigmoid or rectum seemed to be a factor Later in 1924 he had two more cases Now after an interval of 15 years he had met with another Summing up he said that in each of the 6 patients the mass was large enough for him to diagnose a pelvic tumour In 5 the pain was on the left side. In the first 3 he had excised the veins and not cured the patient In the others a more drastic procedure had cured the symptoms He said that the ætiology was obscure. There was no pronounced laxity of the pelvic floor He thought treatment was unsatisfactory and that the condition was more common than generally supposed

Mr J E STACEY thought that the condition was very common and due to coitus interruptus Examination in the erect position was valuable in diagnosis In his opinion only a hysterectomy would cure a severe case.—Mr T F TODD also thought these cases were due to an unsatisfactory sex life —Prof PHILLIPS said that it was noteworthy that the patient complained of pain the moment she stepped out of bed. He had rarely excised the veins in older women if there was a prolapse he did a vaginal hysterectomy

Prof FLETCHER SHAW in reply said that he was doubtful about coitus interruptus being the main cause; of his first three cases two were virgo intacta.

Sarcoma of Ovary and Lung

The PRESIDENT showed a specimen of malignant tumours of the ovary and lung in a girl aged 12

The patient was sent to him with a history of loss of weight and a rapidly swelling abdomen for some months She had recently developed a pain in the left chest slight cough and blood-stained sputum Menstruation had not yet commenced. On examination she was cyanosed and had a pulse rate of 130 The abdomen was fully occupied by a painful and cystic tumour Free fluid was present Dr Bride said he thought the diagnosis lay between a tubercular ascites and pleurisy or an ovarian dermoid or sarcoma of the ovary He performed a laparotomy and found a soft ovarian tumour the size of a football. The tumour was removed without difficulty A needle was passed into the left pleura and some blood stained fluid withdrawn The patient was much relieved for a few days, but she died on the eleventh day from a profuse hæmoptysis

Dr Bride showed three sections two from the ovarian tumour and one from a nodule in the lung He said that in his opinion the case was one of a mixed celled sarcoma of the ovary with secondary deposits in the lung He said that ovarian tumours were not uncommon in young girls. Bland Sutton had referred to a hundred cases of ovariotomy in girls under 15 Of these 41 were simple cystadenomata, 38 were typical dermoids and the remaining 21 were sarcomata Dr Bride said that sarcomata occurred much earlier than carcinomata the majority at the age of puberty They were usually bilateral round celled and extremely malignant. Solid ovarian teratomata contained embryonic tissues from all the layers of the blastocyst They were frequently malignant with sarcomatous metastases Chorion epithelioma of the ovary might represent a form of teratoma

Operation for Prolapse

Mr ST GEORGE WILSON showed a cinematograph film of the interposition operation for prolapse He said that it was especially indicated in cases with a big cystocele which were difficult to cure by Fothergill s operation without unduly narrowing the vagina. A second important indication was that the patient should have passed menopause If the cervix was elongated it should be amputated in the usual way He described his technique and said it was as practised and described by the late Prof Blair Bell.

Prof FLETCHER SHAW said he thought a reasonable criticism of the operation was that after it had been completed the cervix could still be pulled down to the vulva He thought the operation must be restricted entirely to women beyond the menopause

Dr S B HERD thought there were two indications for the operation (1) a previous failure with colporrhaphy and (2) a retroflexed uterus that needed suspension He had had more difficulty with micturition in his cases after this operation than after colporrhaphy

Mr STACEY said he had seen a case of pregnancy after this operation There had been no difficulty during pregnancy but a Cæsarean section was required —Mr W GOUGH had seen one case where a carcinoma corporis occurred after the operation.

Mr WILSON said that in his opinion a bulky uterus was a contrary indication He thought that even with a small uterus the operation was useful as in most cases cystocele was the main trouble, and the use of this operation obviated making the vagina too small. He said that he always amputated the cervix in these cases

REVIEWS AND NOTICES OF BOOKS

British Encyclopædia of Medical Practice

Vol II By Various Authors Under the general editorship of Sir HUMPHRY ROLLESTON, Bart , G C V O K C B , M D , D Sc Emeritus Professor of Physic Cambridge With the assistance of Prof F R FRASER M D F R C P , Prof G GREY TURNER, M S , F R C S , Prof JAMES YOUNG, D S O , M D F R C S L , Sir LEONARD ROGERS K C S I , F R C P , F R C S , F R S and F M R WALSHE *O B E M D , D Sc , F R C P* London Butterworth and Co , Ltd 1936 Pp 767 35s

THE second volume of this important work, with its formidable array of editorial and contributory talent opens with an article on apraxia by Macdonald Critchley and takes us as far as carriers in infective disease by J A Arkwright It may be remarked in passing, that the alphabetical method of describing diseases produces some strange bedfellows for we find athetosis hobnobbing with athletics backache with baker's itch, biliousness with birth palsy, and caisson disease metaphorically rubbing shoulders with cancer But this, though in itself a little disconcerting at first, is no great matter a more real objection to the system is that it necessitates much cross reference which may prove exasperating to the earnest student who for example if he turn up bacilluria ' is referred to coliform bacillary infections ' which is in another volume The articles themselves, however, are as good as they ought to be Perhaps of special value to practitioners might be mentioned W S C Copeman s on rheumatoid arthritis which is full of sound sense and free from fads and A G Timbrell Fisher's on osteo arthritis Another interesting article is that by J B Mennell on the treatment of backache and lumbago by various manipulative and supporting measures which is illustrated with some excellent sketches G W Bray deals fully with the vexed problem of asthma, and occupational disease is well represented by W E Cooke s article on asbestosis, illustrated with some beautiful microphotographs taken by the author and C F Hill C P Symonds and Hugh Cairns collaborating on the subjects of brain abscess and brain tumour supply a valuable note on the use of hypertonic salt solutions for temporarily relieving increased intracranial tension by which means a comatose patient will usually recover consciousness for long enough to coöperate in a neurological examination In the article on cancer by W I Gye and John Hosford the modern methods of treatment, including the radium " bomb," are well summarised T S Rippon s article on aviation describes the existing scheme for the examination of pilots the methods used for examining the special senses and the special tests of fitness for aerobatics which demand normal circulatory and muscular tone combined with good abdominal muscles It seems that blacking out due to cerebral anæmia can be hindered or prevented by contracting the abdominal muscles and so raising the intra abdominal pressure In the sphere of pediatrics Alan A Moncrieff writes on Still s disease and cancrum oris and Norman B Capon on asphyxia in children J F Halls Dally writes sanely on blood pressure high and low and C J Lakin on arterial disease and degeneration Athletic injuries by W F Tucker and athletics by Adolphe Abrahams with a note on the nervous factor in sport go to show that the English can still take their pleasures sadly Abrahams is an opponent of strenuous sport for women on the ground that it " diverts energy from channels for which it is specially required," by which presumably he means childbearing Quite apart from the fact that, under existing conditions, *a large number of women, condemned to childlessness* seek an outlet for their energies in athletics, the contention that the habit of taking strenuous exercise makes for difficult labour is quite unsupported by evidence

Inorganic Chemistry

A Survey of Modern Developments

By SIR GILBERT MORGAN, D Sc , LL D , F R S , Director of Chemical Research , and F H BURSTALL, M Sc , A I C , both of the Department of Scientific and Industrial Research of the Chemical Research Laboratory, Teddington Cambridge *W Heffer and Sons, Ltd 1936 Pp 462 15s*

THE main function of this book is to illustrate the statement that the type of chemical combination designated by the chemist as " coördination " is not merely characteristic of substances like cobalt ammines, but actually enters into the everyday laboratory experience of many branches of pure and applied chemistry In an introductory chapter the classification of the elements and the interpretation of chemical valency in terms of the electronic structures of the atoms are summarised. In the next ten chapters the various types and structures of the compounds formed by the individual elements are dealt with systematically, following the periodic order of the elements Special attention is given to recent advances in this subject and to the discussion of the coördination compounds of the elements The latter part of the book is devoted to the description of coördination compounds employed in the arts and industries and of compounds of particular types—e g , the carbonyls and nitrosyls The final chapter on the organic derivatives of metals and metalloids, many of which (e g , arsenicals and mercurials) are therapeutic agents, contains much matter of direct medical interest The book summarises an enormous amount of information which is of considerable interest to the chemist, but mostly too highly condensed and recapitulatory in style for the general reader The chapters on the isotopes of hydrogen and heavy water, however, and on the natural and artificial transmutation of the elements give useful accounts of some of the more outstanding recent developments in this field of inorganic chemistry

The Art of Treatment

By WILLIAM R HOUSTON, A.M , M D , F A C P , formerly Professor of Clinical Medicine, University of Georgia , formerly Visiting Professor of Medicine, Yale in China London Macmillan and Co , Ltd 1936 Pp 744 21s

IN spite of the truth of the statement that the main essential of treatment is diagnosis, the best management of a sick man is not a simple corollary of a correct diagnosis but an art which can be learned only through study and practice The medical schools probably deserve the criticism made by others as well as by Dr Houston that they pay too little deliberate attention to the teaching of treatment , the medical staff leaves half the treatment of inpatients to the nurses, and it seldom undertakes the full prolonged responsibility of looking after an out-patient in the way that a good family doctor would do it

Dr Houston's book is an attempted answer to this criticism. It is written for students and young doctors who already know something of medicine of pharmacology and of therapeutic technique It is concerned with the approach to the patient the art of using all that knowledge to the maximum advantage in his particular case A long introduction deals with general principles which range from the dosage of drugs to the question of doctors fees the writing is discursive with a certain conscious brightness, but the plea that treatment needs to be thought about more thoroughly and more honestly, is undoubtedly sound. The body of the book deals in turn with the broad subdivisions of therapeutics under which diseases roughly group themselves according to the chief mode of treatment they call for There are the patients who are to be treated mainly by nursing care diseases amenable to specifics conditions in which the chief therapeutic method is psychotherapy or guidance—this section occupies one third of the book conditions where treatment mostly means a limitation of life conditions where treatment is largely based on physiological considerations and finally conditions in which treatment is tentative and experimental. The discussions are fairly full, the style easy almost conversational, with frequent use of anecdote or illustrative case history and the author is concerned more with his general point of view than with comprehensiveness of detail. The book certainly exemplifies the American willingness to discuss at length matters which the Englishman either does not think about or takes for granted but if we admit the criticism of the schools which it is written to meet, we must welcome it as a helpful contribution to the teaching of therapeutics. There can be no quarrel with this generalisation of the author's "It comes out that most therapeutic conceptions and plans are simple that success turns mostly on doing simple things well

Die "atypische" Pneumonie

By Dr Frank Kellner, Facharzt für Lungenkrankheiten Leitender Arzt der Tuberkulose Fürsorgestelle Kassel Munich Otto Gmelin. 1936 Pp 52 M.2 70

Chest physicians have long been familiar with forms of pulmonary inflammation which do not fit in with the classical descriptions of lobar or broncho pneumonia. Often these atypical pneumonias begin with a short mild febrile attack accompanied by cough but in some the course is afebrile throughout Physical signs are few although X ray examination shows an opaque area usually near the hilum but quite common in any of the lobes Resolution takes place in the course of a few weeks and the chief interest in the condition lies in the difficulty of distinguishing it from an early tuberculous infiltration

Dr Kellner considers that recent epidemics described as influenza and characterised by inflammatory processes of the upper respiratory tract, the bronchial tubes and the lungs have included so large a percentage of these atypical pneumonias that the term atypical should no longer be applied to them The few physical signs combined with the fact that these patients rarely undergo X ray examination rather than its rarity accounts for the scanty attention paid to the clinical differentiation of this condition. Although it is occasionally difficult to distinguish between pneumonic consolidation and tuberculosis of the hilar glands it is chiefly in the initial infiltration type described by Assmann that confusion occurs The absence of upper respiratory and bronchial inflammation and the predilection of tuberculous infiltrations for peripheral and especially subclavicular sites may help in the diagnosis but often, according to Dr Kellner it is only possible to distinguish the conditions by following on the screen the course they pursue He thinks that many of the cases of initial infiltration which are said to have cleared up in a few weeks have really been patches of non specific inflammation.

His brochure which is illustrated by a small number of carefully selected and well reproduced radiograms provides a useful summary of our knowledge on this interesting and important subject.

Manual of Public Health Laboratory Practice

By J R Currie, Henry Mechan Professor of Public Health University of Glasgow Edinburgh E and S Livingstone 1936 Pp 378 21s

The design is to cover the field of laboratory work with which those engaged in public health work or proposing to acquire a D.P H must be acquainted. The author succeeds in producing a manual in which no aspect of laboratory work connected with public health escapes adequate notice, and has outlined technical details so clearly as to provide a guide to anyone who knows his way about a laboratory The indications suggested for the use of the various procedures and the interpretation of the results are orthodox and sound. Sections are included on entomology and meteorology which contain useful matter rarely to be found except in more specialised works The appeal of this book will not be to laboratory workers only To the practising medical officer of health it will prove invaluable

The Principles of Dental Medicine

Second edition By F W Broderick, M R C S L R.C P L D S Hon Dental Surgeon to the Royal Victoria and West Hants Hospital. London: Henry Kimpton. 1936 Pp 575 30s

Dr F W Broderick was one of the first to expound the view that dental disease is due to a local expression of general disease This thesis was elaborated in a book which appeared in 1928 under the title Dental Medicine While the main concept remains the same in this second edition Dr Broderick slightly changed the title and has added so much new matter that he has produced what is practically a fresh book He claims that his goal has been reached and that dental medicine in contradistinction to dental surgery is now a practical proposition

The book is divided into three parts In the first the writer describes certain biochemical factors which he regards as causative in many forms of dental disease blood reactions colloidal states the endocrine and vegetative systems and calcium metabolism The amount of evidence he adduces to support his theories is impressive in its bulk but many of the views he quotes are individual ones which are themselves open to criticism The second part deals with ætiology and treatment both remedial and preventive of dental disease and represents the application of the principles enunciated in the first part Dental caries and pyorrhœa are in Dr Broderick's view essentially due to a disturbance of colloidal equilibrium which affects the acid base balance of the blood If a condition of acidosis is produced by such disturbance the end result so far as the teeth are concerned is dental caries, on the other hand, a state of alkalosis is thought to lead to pyorrhœa Dr Broderick has now linked up his work with the views expressed by Dr J R McDonagh and appears to accept completely the latter's concept of disease In treatment a variety of methods is recommended in which dentistry as usually understood plays little part Alkalis such as sodium bicarbonate are used with a view to the prevention of caries and derivatives of cholin and ergot in cases of rampant caries Dr Broderick advocates the administration of small doses of insulin to children with extensive caries on the assumption that caries is due to a dehydration of the colloid particles and that insulin will bring about hydration For pyorrhœa he recommends ammonium chloride, thyroid extract and colonic lavage, and follows up this treatment by subcutaneous injections of various kinds There seems to be little scope for the ordinary methods of dentistry in his concepts of dental disease The illustrative cases recorded seem to have shown considerable improvement while under treatment along the lines suggested

Cosmetic Dermatology

By Herman Goodman, B S, M D London McGraw Hill Publishing Co, Ltd 1936 Pp 591 36s

At first glance this book is likely to bewilder the reader, for Dr Goodman has apparently cut himself adrift from all ordinary conventions of text book arrangement But the knowledge he displays is prodigious even if his method of imparting it is peculiar Not only physicians and dermatologists but beauty specialists and students of cosmetics should be grateful to him, for here at last, combined with a wealth of cosmetic pharmacy, is just the type and quality of honest dermatology they need They will learn for instance what a "pore" really is, and why when enlarged" it cannot be ' shrunk.' The swindle of bleaching by creams and lotion is also exposed, and the futility of attempts to feed the skin from without, or to eliminate wrinkles by tissue or muscle oils It is easy to see that the author is a dermatologist at heart, although unlike most of them he has not scorned to acquire some knowledge of cosmetics

Part I of his work is a dictionary of ingredients, in alphabetical order from acacia to zinc sulfide (so spelt) All those commonly used by dermatologists as well as manufacturing chemists are set out, although it is not clear why such proprietary injections as Afenil or ointments such as Cycloform should be included under their manufacturers' names, while strontium bromide is not alloted its proprietary name of Lkzebrol The author does not limit his observations to the scope suggested by his title, no self respecting beauty specialist is likely to be called upon to treat infantile eczema

In Part II the ingredients previously considered are combined in "tested formulæ' and attached in groups of 6 to 20 to the particular disease or "blemish" under consideration These again are arranged in alphabetical order beginning with acne and ending with vanishing creams and vitamins All that pertains to cosmetics is discussed depilatory, dusting and face powders, hair dyes, lipsticks, eye preparations including eyewash, eye tissue cream, eye-shading bases eyebrow creams, eyelash oil, even a "pain reducer" for eyebrow epilation We deprecate the inclusion of chapters on the treatment of burns, poison ivy, psoriasis, scabies, ringworm, and wounds, for it is surely unwise to encourage experts in cosmetics to make diagnoses and recommend the treatment for diseases, infections, and injuries

Appendices on cosmetic colours derived from different sources, on perfumery and on weights and measures conclude the book, which is likely to appeal not only to dermatologists and cosmetic specialists but also to the laity

Blood Cultures and their Significance

By Hildred M Butler, B Sc Melbourne, Bacteriologist, Baker Institute of Medical Research, Alfred Hospital, Melbourne London J and A Churchill Ltd 1937 Pp 327 15s

Blood culture has been a routine procedure in clinical bacteriology for many years, but in many institutions its importance has not been fully realised either by clinician or bacteriologist Possibly this is because nobody is particularly interested The clinician asks for a blood culture not really expecting to obtain much information The bacteriologist does the culture in something of the same spirit, and mostly the result is either negative or negligible in the sense that a growth of non pathogenic organism is obtained The clinician's scepticism as to the value of blood cultures is partly at least attributable to lack of pains in the bacteriologist to ensure that the best cultural results are obtained with the minimum of contamination Miss Butler, following a study and trial of published methods, has here laid down an efficient technique whereby fallacious results could be largely avoided It may well be that some of the methods she describes could be further improved by the use of devices elaborated by individual workers who have not published them in detail, but for the omission of unpublished methods Miss Butler can hardly be blamed Quite apart from technique the practising bacteriologist can find here a useful summary of the results which have been achieved by blood culture in almost all conditions The interesting chapter on bacteræmias following operative procedures deserves attention of surgeons and dental surgeons

A book of this description serves as a reminder of the results achieved by blood culture, and no bacteriologist, however senior will feel that the time spent in reading Miss Butler's book has been wasted

Physician, Pastor, and Patient

By George W Jacoby, M.D, Past President of the American Neurological Association and the New York Neurological Society London and New York Paul B Hoeber (Medical Book Department of Harper Bros) 1936 Pp 390 15s

This considerable volume represents the musings of a wise physician over a wide field of medicine in its social and religious relationships, and inasmuch as the author casts his eye over the whole history of culture, he displays a wide, if not penetrating, erudition In surveying the health of mankind from one part of the world to another, he maintains an attitude which is dignified and catholic in taste and tolerance The scattered wisdom in this book is not sufficiently well integrated for one to make out a consistent philosophy of medicine, but many readers will find entertainment both in the text and in the charming illustrations drawn chiefly from Oriental art

THE LANCET

ERGOTAMINE TARTRATE FOR MIGRAINE

In 1934 BROCK O SULLIVAN and YOUNG reported that ergotamine tartrate was effective in cutting short an attack of migraine. This discovery was made empirically after the trial of a number of substances reputed to be of value, and has since been confirmed by other workers. Dr MARY E. O SULLIVAN[1] has recently reported the results of the trial of this remedy in a larger series of cases. Over a period of two years 97 patients were treated for 1132 headaches and 89 of these were relieved of a total of 1042 attacks which has been calculated as a saving of 30 000 hours of suffering. The subcutaneous method of administration of the drug was found to be more effective than the oral relieving a larger proportion of patients and giving relief more quickly. An initial subcutaneous dose of 0 25 mg was given and repeated after two or three hours if the headache persisted or later if it returned. It was rarely necessary to give more than 0 5 mg in a single dose, but the longer after the onset of the attack the treatment was given the larger the dose needed. For oral administration as many as five 1·0 mg tablets might be necessary in a single dose to cut short an attack.

On another page is a letter from Dr T W GORDON KELLY describing his experience of ergotamine tartrate in the treatment of his own migraine. Finding that this drug would cut short his headaches after many other remedies had proved useless he tried it as a prophylactic taking 0 25 mg subcutaneously at bedtime on the eve of a busy day and found that in this way he could guarantee himself a day free from headache. After the frequent administration of ergotamine tartrate for many months he has experienced no ill effects either immediate or remote. Dr O SULLIVAN discusses the prophylactic use of this drug and advises against it. It must be remembered that few sufferers from migraine have headaches as frequently as Dr KELLY and the regular administration of such a powerful substance for many years to avert attacks occurring only at intervals of weeks or months is clearly undesirable. Moreover, since in almost all cases an attack can be aborted within an hour or so by this treatment it is more economical to cut short an attack when it arises. The prophylactic use of ergotamine therefore though interesting is not widely applicable. Dr KELLY confirms the observation that ergotamine tartrate is far more effective when given subcutaneously than when swallowed. This may be because during an attack of migraine when nausea is present, and still more after vomiting has occurred absorption from the stomach is impaired. At this stage, in fact ergotamine may make the vomiting worse without improving the headache. Dr KELLY's note that sublingual administration is far superior to ingestion will if generally true prove of considerable value since it will make the patient independent of the doctor's hypodermic needle and enable an effective dose to be taken at the earliest possible moment. Also the effective dose is less two tablets given sublingually being equivalent to the five or six found necessary if the drug is swallowed.

The mode of action of ergotamine is at present unexplained. It has proved useless for the relief of headaches due to conditions other than migraine and has no analgesic properties. Originally employed on the hypothesis that it inhibited the nerve-endings of the sympathetic it has been shown by P SOLOMON[2] to be without effect on the psycho galvanic reflex, which is an index of sympathetic activity and to relieve the headache without influencing the sympathetic nervous system as a whole. Dr O SULLIVAN believes that the action of the alkaloid is dependent on the humoral state of the organism and is intimately connected with the complex mechanism of the still unexplainable migraine seizure'. Medical sufferers from migraine who are acquainted with the work of G W PICKERING and others on the production of headache with histamine can hardly have failed to be struck by the resemblance between the brief headache induced by the intravenous injection of histamine and the migrainous headache. Histamine headache has recently been further studied by CLARK HOUGH and WOLFF[3] who have confirmed the observations of PICKERING and HESS, and support their inference that this type of headache is due to dilatation and stretch of the pial and dural arteries and their surrounding tissues. In migraine as in the histamine headache dilatation and increased pulsation of the temporal arteries occurs and it seems reasonable to infer that the state of the intracranial arteries is similar in the two conditions. It is possible that ergotamine acts by restoring tone to the stretched smooth muscle of the intracranial arteries and observations on the effect of ergotamine on the histamine headache would be valuable. Ergotamine though of outstanding value as a palliative does not cure migraine but the elucidation of its mode of action might bring us nearer to the understanding of the nature of the disorder. The suffering social inconvenience and economic loss occasioned by migraine must in the aggregate be enormous. A patient with the disorder in a severe form is subject at frequent intervals for the greater part of a lifetime to pain discomfort, and incapacity as severe as those experienced by many patients with an intracranial tumour. Denied even the colloidal equilibrium which affects the acid base balance of the blood If a condition of acidosis is produced by such disturbance, the end result so far as the teeth are concerned is dental caries, on the other hand, a state of alkalosis is thought to lead to pyorrhoea Dr Broderick has now linked up his work with the views expressed by Dr J R McDonagh and appears to accept completely the latter's concept of disease In treatment a variety of methods is recommended in which dentistry as usually understood plays little part Alkalis such as sodium bicarbonate are used with a view to the prevention of caries and derivatives of cholin and ergot in cases of rampant caries Dr Broderick advocates the administration of small doses of insulin to children with extensive caries on the assumption that caries s due to a dehydration of the colloid particles and that insulin will bring about hydration For pyorrhoea he recommends ammonium chloride, thyroid extract, and colonic lavage, and follows up this treatment by subcutaneous injections of various kinds There seems to be little scope for the ordinary methods of dentistry in his concepts of dental disease The illustrative cases recorded seem to have shown considerable improvement while under treatment along the lines suggested

ERGOTAMINE TARTRATE FOR MIGRAINE

In 1934 Brock O Sullivan and Young reported that ergotamine tartrate was effective in cutting short an attack of migraine This discovery was made empirically after the trial of a number of substances reputed to be of value and has since been confirmed by other workers Dr Mary E O Sullivan[1] has recently reported the results of the trial of this remedy in a larger series of cases Over a period of two years 97 patients were treated for 1132 headaches and 89 of these were relieved of a total of 1042 attacks which has been calculated as a saving of 39 000 hours of suffering The subcutaneous method of administration of the drug was found to be more effective than the oral, relieving a larger proportion of patients and giving relief more quickly An initial subcutaneous dose of 0 25 mg was given and repeated after two or three hours if the headache persisted or later if it returned It was rarely necessary to give more than 0 5 mg in a single dose but the longer after the onset of the attack the treatment was given the larger the dose needed. For oral administration as many as five 1 0 mg tablets might be necessary in a single dose to cut short an attack.

On another page is a letter from Dr T W Gordon Kelly describing his experience of ergotamine tartrate in the treatment of his own migraine Finding that this drug would cut short his headaches after many other remedies had proved useless he tried it as a prophylactic taking 0 25 mg subcutaneously at bedtime on the eve of a busy day and found that in this way he could guarantee himself a day free from headache After the frequent administration of ergotamine tartrate for many months he has experienced no ill effects, either immediate or remote Dr O Sullivan discusses the prophylactic use of this drug and advises against it It must be remembered that few sufferers from migraine have headaches as frequently as Dr Kelly and the regular administration of such a powerful substance for many years to avert attacks occurring only at intervals of weeks or months is clearly undesirable Moreover since in almost all cases an attack can be aborted within an hour or so by this treatment it is more economical to cut short an attack when it arises The prophylactic use of ergotamine therefore though interesting is not widely applicable Dr Kelly confirms the observation that ergotamine tartrate is far more effective when given subcutaneously than when swallowed This may be because during an attack of migraine when nausea is present, and still more after vomiting has occurred absorption from the stomach is impaired At this stage, in fact ergotamine may make the vomiting worse without improving the headache Dr Kelly's note that sublingual administration is far superior to ingestion will if generally true prove of considerable value since it will make the patient independent of the doctor s hypodermic needle and enable an effective dose to be taken at the earliest possible moment Also the effective dose is less two tablets given sublingually being equivalent to the five or six found necessary if the drug is swallowed

The mode of action of ergotamine is at present unexplained It has proved useless for the relief of headaches due to conditions other than migraine and has no analgesic properties Originally employed on the hypothesis that it inhibited the nerve-endings of the sympathetic it has been shown by P Solomon[2] to be without effect on the psycho galvanic reflex which is an index of sympathetic activity and to relieve the headache without influencing the sympathetic nervous system as a whole Dr O Sullivan believes that the action of the alkaloid is dependent on the humoral state of the organism and is intimately connected with the complex mechanism of the still unexplainable migraine seizure Medical sufferers from migraine who are acquainted with the work of G W Pickering and others on the production of headache with histamine can hardly have failed to be struck by the resemblance between the brief headache induced by the intravenous injection of histamine and the migrainous headache Histamine headache has recently been further studied by Clark Hough and Wolff[3] who have confirmed the observations of Pickering and Hess and support their inference that this type of headache is due to dilatation and stretch of the pial and dural arteries and their surrounding tissues In migraine as in the histamine headache dilatation and increased pulsation of the temporal arteries occurs and it seems reasonable to infer that the state of the intracranial arteries is similar in the two conditions It is possible that ergotamine acts by restoring tone to the stretched smooth muscle of the intracranial arteries and observations on the effect of ergotamine on the histamine headache would be valuable Ergotamine though of outstanding value as a palliative does not cure migraine but the elucidation of its mode of action might bring us nearer to the understanding of the nature of the disorder The suffering social inconvenience and economic loss occasioned by migraine must in the aggregate be enormous A patient with the disorder in a severe form is subject at frequent intervals for the greater part of a lifetime to pain discomfort and incapacity as severe as those experienced by many patients with an intracranial tumour Denied even the

dignity of a bad prognosis he, or more often she, is likely to exhaust the sympathy of friends and relatives and to feel a recurrent nuisance—no more use, in fact, during the attack than a sick headache To be able to offer such unfortunates a reliable palliative is much, but it is to be hoped that the need for systematic investigation of the ætiology of migraine will not be overlooked

NEW LIGHT ON THE LIFE CYCLE OF THE MALARIA PARASITE

It has long been a source of interest to the biologist and of chagrin to the clinician that the malaria parasite, when banished from the blood stream by quinine, is able somewhere to maintain its existence That the parasiticidal effect of quinine has been at the same time so complete and yet so futile is one of the notable mysteries of clinical medicine If it is true that the sporozoites injected by the mosquito complete their life cycle in the cells of the circulating blood, then the infection should be scotched by the ingestion of quinine sufficient to maintain a lethal concentration in the blood stream And yet a patient who has taken a gramme of quinine daily before and during infection by mosquito bites, and for every day throughout the incubation period, develops an attack of malaria precisely as if no drug had been given The life history of the parasite in the vertebral host cannot then be as obvious as all that, for, though **Schaudinn** described the penetration of sporozoites into red blood corpuscles, no one it seems has succeeded in repeating his observations

Some years ago Lieut Colonel S P **James** made the suggestion[1] that the sporozoites, when they are injected by the mosquito, may be carried to reticulo endothelial cells of the lungs and other organs in which they complete their asexual cycle of growth and sporulation—a process already observed in the bird parasite, halteridium Colonel **James** has now confirmed this suggestion for a malaria parasite itself—not in man, but in the domestic fowl At a laboratory meeting of the Royal Society of Tropical Medicine and Hygiene on March 18th he demonstrated the life-history of the *Plasmodium gallinaceum* as worked out by Mr P **Tate**, Ph D, and himself at the Molteno Institute in Cambridge Using this avian strain, brought from Ceylon by Prof **Brumpt** of Paris, **James** and **Tate** have witnessed a cycle of development occurring, not in red blood cells, but in the reticulo-endothelial cells of the spleen, liver, kidneys, and particularly the endothelial cells lining the capillaries of the brain In chickens which had died of a malarial attack, despite the destruction by quinine of all the parasites in the peripheral blood, they found the capillaries of the brain blocked with masses of schizonts, the result being death from paralysis and coma Those who were able to study the slides submitted at the laboratory meeting were left in no doubt that in avian malaria there is a schizogenous cycle of development occurring in reticulo-endothelial cells Parallel observations have been made for the blood-forming cells by two Chicago workers[2] and for the reticulo-endothelial cells by **Raffaele**[3] in Rome **James** and **Tate** have observed the entry of the parasite into blood-forming cells, and every stage in their growth and multiplication until the merozoites burst the cell and are ready to enter other endothelial cells and red blood cells, to begin the cycle anew

But while this is true of certain avian parasites it may not apply to those of man, although there is some justification for thinking that it may, if, as we believe, it is a fact that the three fundamental discoveries in malaria—associated with the names of **Ross**, **McCallum**, and **Roehl**—were made first in birds and only afterwards in man If the analogy should prove true, the discovery affords no short cut to treatment But any light shed on the life history of malaria parasites should indicate the direction in which successful treatment lies, for a drug which circulates only in the blood stream cannot effectively attack extra hæmic parasites In the meantime the biologist may have to revise the classification of plasmodia in view of their affinity for tissue cells

SILICOSIS IN THE RAND GOLD MINES

Since the inception in 1916 of the Miners' Phthisis Medical Bureau[4] of the Union of South Africa elaborate records have been kept of the incidence of silicosis and tuberculosis on the Rand, and of the fate of those afflicted, in so far as they could be traced The report, signed by Dr L G **Irvine** the chairman of the Bureau, on the three years ended July 31st, 1935, recently issued, contains, like its predecessors, a summary of the more important data for the whole period It is thus possible to get an idea of the trends in the character and incidence of silicosis in the mining population of the Rand and to form an estimate of the value of this great medical organisation in its twofold function (1) to award certificates which enable those who have contracted the disease to get compensation, and (2) to help in its control and prevention. The legislation which led up to the establishment of the Bureau is set out on p 773 with some account of the corresponding developments in this country Inasmuch as there is clearly a need for the extension of these, it is from every point of view worth investigating the results achieved in South Africa, where the preventive measures and the rigid supervision of the Rand miners seem to have been to some extent effective in combating the disease The improvement in working conditions on the Rand in recent years is shown by the great increase in the average period of service underground before the incidence of the disease The mean duration of the previous underground service in all new cases of silicosis among miners who have worked only in scheduled mines was 9¼ years in 1919–20, and as much as 16¾ in 1934–35 the commonest duration being 18 years and the longest 28 years It must be understood, of course that these data refer only to the previous service of men who actually contract silicosis and take no account of the services of the great majority whose lungs were not and may never be affected It should be noted too that a diagnosis of silicosis is recorded when the earliest definite signs are detected at the periodical examinations submission to which is a condition of employment The number of cases of silicosis which have arisen since 1919 when the Act was passed defining three stages of silicosis has been affected in the main by two factors whose influence has been conflicting a decided and progressive decline in the liability to contract silicosis and on the other hand an increase in the number of miners who have worked continuously for long periods in the mines As a result of the predominating effect of the second factor, the actual number of new cases of silicosis has increased during the year 1934–35 after an uninterrupted fall from 364 in 1926–27 when 13 525 miners were examined to 180 in 1933–34 when 19,731 miners were examined In 1934–35 the new cases numbered 193 amongst 21 812 The increase (of 13 cases) is attributed to a substantial increase in the number of miners with over 18 years service and a slightly higher incidence of silicosis amongst them It is satisfactory to learn that in all the new cases the disease was in the earliest stage

[4] Report upon the work of the Miners Phthisis Medical Bureau for the three years ended July 31st 1935 Pretoria Government Printer 1936

Tuberculosis is classified for the purposes of the Bureau as occurring with silicosis and alone Patients with either form are eligible for compensation and are excluded from further work in scheduled mines as soon as their disease is detected while patients with simple silicosis are allowed to continue at work During the three years under review, 7 cases of tuberculosis with silicosis were detected in white men, of these 5 had previously been notified as having silicosis The production rates " (incidence rates) over the period averaged 0·115 per 1000 Tuberculosis alone was detected during the three years in 81 cases, giving prevalence rates for each year of 1 79 1 10 and 1 18 per 1000 respectively The experience of the Bureau has shown that a considerable proportion of cases which at the outset manifest the clinical and radiological signs only of tuberculosis later on present evidence of the development of an element of silicotic fibrosis also For purposes of compensation these cases are immediately transferred to the class of tuberculosis with silicosis' The native labourers numbering during 1934–35 255,816 also undergo initial and periodical examinations, and a final examination on the termination of their underground employment These examinations are carried out by 42 whole time medical officers from the medical staff of the mines and of the central hospital of the Witwatersrand Native Labour Association. Their task is onerous inasmuch as nearly 90 per cent. of this native labour force is replaced each year Amongst this shifting population the prevalence rates for tuberculosis have shown a lower trend since 1928, the combined rates for tuberculosis and tuberculosis with silicosis reached the lowest recorded figure in 1934–35 (for all forms of silicosis 1 97, and for all forms of tuberculosis, 3 23 per 1000) being less by at least 40 per cent than it was ten years ago. The great preponderance of cases of active tuberculosis amongst the compensatable diseases leads Dr IRVINE to emphasise once more the cardinal importance of directing all possible effort to the elimination of cases of communicable tuberculosis amongst native mine-workers and of bringing under control all occupational and other conditions which can be shown to foster the incidence of that infection amongst them.

In view of this encouraging evidence, can it be said that the production of silicosis has been arrested in the mines on the Rand? Unfortunately not, amongst the white 'new Rand miners' (that is, those recruited since 1916 and subjected to an initial examination, periodically repeated throughout the whole period of service) who have been more or less continuously at work for periods of 16 to 18 years it is stated that "the incidence of silicosis has become significant" The Bureau suggests that since in respect of these men the medical prophylactic measures may be presumed to have done their best, any further improvement will have to come from the technical side of dust prevention. It is fortunate that at this stage the help is available of an expert physicist, appointed by the Transvaal Chamber of Mines who are undertaking a thorough reinvestigation of the problem of dust production in the mining processes By means of the thermal precipitator instrument developed under the auspices of the Medical Research Council[4] a more complete understanding of the problem of dust production will be gained and this should lead, in turn to the development of an efficient system of dust suppression. The value of the records and experience of an established organisation such as this Bureau in assessing the effect of new technical measures is inestimable and Dr IRVINE and his colleagues can be assured that their work is appreciated not only in the Transvaal but throughout the world wherever silicosis is a problem.

AT a meeting of the Royal College of Physicians of London held on March 22nd Lord Dawson was re-elected President.

Mr H. L Eason vice-chancellor of the University of London and medical superintendent of Guy's Hospital has been appointed principal of the university from July 1st 1937 to Sept 30th 1941 in succession to the late Sir Edwin Deller

IN a recent report of the annual dinner of the Royal London Ophthalmic (Moorfields) Hospital an allusion to the resignation of Dr Russell Brain from the staff of the hospital might from its wording imply that he had retired from the medical profession. This all will be glad to know is not the case

ANNOTATIONS

AN ADVISORY FACTORIES COUNCIL

MOST practitioners have suffered from apparently arbitrary decisions given by State Departments upon matters in which the decision of a minister of the crown is final The Ministry of Health in its relationships to insurance practitioners is one case in point, another is the relation of the Ministry of Pensions to ex Army pensioners and their claims The decisions given may be right or they may be wrong, in either case a feeling is left that impartial justice has not been administered In industry we hear criticisms of the method by which certain regulations have been made and administered, new industrial processes, it is said have been stifled by the exacting nature of certain regulations These criticisms may be—and often obviously are—unfounded But is there not a way out? There are nowadays statutory advisory councils and advisory committees for almost every conceivable subject of legislation agriculture cinematograph films, the dye stuffs industry, forestry, housing, import duties, traffic regulation, plumage importation, poisons, shipping unemployment insurance, and so on It may usefully be recalled, too, that the report of the Committee on Ministers' Powers (a valuable State document published in 1932, of which too little notice has been taken) observed that the practice of consultation between a department and the particular interests affected by a proposed exercise of delegated law making power should be "extended so as to ensure that such consultation takes place whenever practicable" It seems to us that a strong case could be made out for an advisory council which might lessen, if it could not share, the responsibility placed upon the Secretary of State and the Home Office inspectorate under the Factories Acts and the idea has influential support[1] It remains to inquire what kind of questions such an advisory body should be competent to consider In the new Factories Bill a clear and very important distinction is drawn between regulations which can be made by the Secretary of State without formal inquiry and *special* regulations which can only be made after the issue of draft regulations (see second schedule to the Bill) The procedure proposed is for the Secretary of State to issue a draft of the regulations, stating a time during which an objection may be lodged On the receipt of an objection the Secretary of State may amend and reissue the draft If however a *general* objection is made the Secretary of State shall direct an inquiry to be held before making regulations Or, if he thinks fit he may order an inquiry in the absence of a general objection These inquiries are to be held in public by a competent person, appointed by the Minister who may hear on oath any evidence which in his opinion is relevant It will be important to understand what constitutes a general objection to a draft regulation A general objection may be made either by a majority of the occupiers of the factories affected or by any person who satisfies the Secretary of State that he represents a majority of the persons employed in those factories Furthermore if it appears to the Secretary of State that by reason of special conditions any of the requirements of the draft regulations may be unnecessary or inappropriate to any class or description of factory The Secretary of State may accept a general objection from employees or employed, as in the previous instance It seems to us that under certain easily conceivable circumstances the Secretary of State might prove to be difficult to satisfy The main functions of an advisory board might be (1) to advise him concerning the (ordinary) regulations which he alone is competent to make, e g, the setting up of standards of adequate ventilation, lighting, &c, and the interpretation which inspectors should place upon the necessarily vague definitions contained in the Bill, and (2) to advise him whether or not a general objection to any of his draft regulations has in fact been made out Whatever else an advisory council might do, it would certainly be useful in these two capacities

RHEUMATIC NODULES, SPONTANEOUS AND INDUCED

THE suspicion that since rheumatic nodules tend to occur over pressure points trauma may be a factor in their production is strengthened by some experiments recently carried out by Massell, Mote, and Duckett Jones[1] A series of patients were given injections of 2–3 c cm of their own blood in the subcutaneous tissue of the olecranon region, and for the succeeding ten days the injected elbow was rubbed against the bedclothes for several minutes six times a day In every case a hæmatoma and a diffuse thickening of the subcutaneous tissue were produced which lasted ten days, and then gradually disappeared, some left no trace, others became the site of discrete painless subcutaneous nodules which were indistinguishable clinically from rheumatic nodules Of a group of 20 patients with clinical rheumatic fever, 18 developed induced nodules, 13 out of 26 patients in whom active rheumatism was suspected on laboratory evidence but who showed no clinical signs developed nodules, as did only a few (14 per cent) of a group of choreics and patients with inactive rheumatism Only 1 of a control group of 34 patients of the same age period showed a nodule response, and in this case there was a possibility of the patient having suffered from rheumatic fever Further investigations were made into the nature of the trauma required to produce nodules In active rheumatism neither friction alone nor friction with the injection of novocain had any effect, although nodules appeared in the opposite arm, which received blood also In a small group of cases the injection of saline produced nodules almost as often as did the patients' own blood The authors make no mention of the incidence of spontaneous nodules in the cases under observation, nor, apparently, did they investigate the effect of injecting blood from a non rheumatic patient, if this device were successful it would look as if rheumatic nodules are merely the result of injury in an unusually labile connective tissue, and make less likely the possibility that the nodule is an "allergic response" to the injection of the patients own blood

In another accompanying paper the same authors[2] describe the histology of a number of nodules of varying ages both spontaneous and induced They had the foresight to remove these under nerve block anæsthesia, thus avoiding the tissue distortion which invariably follows local anæsthesia The changes in the natural rheumatic nodule are similar to those described by L Gross and J C Elwlich[3] in the rheumatic myocardium. The fibrous tissue swells and becomes markedly eosinophilic and about the same time there is an infiltration of polymorphonuclear leucocytes and proliferation of perivascular mesenchymal cells, although multinucleate cells of Aschoff-Coombs type are uncommon the vessels show endothelial proliferation and occasionally medial vacuolation. In the later stages there is organisation around the necrotic area with revascularisation and increasing fibrosis The artificial nodules showed a similar morphology but the area of damage was more extensive and much phagocytosis of the blood pigments obscured the picture The histology of the saline-induced nodule is not described Although these observations are of considerable interest there seems little hope of applying them to the practical problem of determining by a simple means whether or not rheumatism is still active

EVERGREEN PEOPLE

The case of a patient contributed by Prof Lawford Knaggs to this issue (see p 745) is a remarkable story from several points of view It is an account of a very uncommon condition it is completed by observations over more than 24 years it is told by a surgeon who has retired from active operating for many years but who has nevertheless retained a keen interest in the study of disease; it adds to our knowledge Infectious non-suppurative encephalitis of this kind must be extremely rare and such complete recovery one would imagine to be rarer still. It is truly remarkable that the brain could bulge through a subtemporal opening on the left side of the skull for as much as 1 in above the surface and yet that there should be so little pressure upon Broca s area that the child could converse intelligently six days after the operation.

Surgeons are often reproached for not knowing the remote results of their operations more accurately Only those who have attempted to learn the histories of urban patients who have been operated upon some years before know how discouraging is the meagre response Some have moved to other districts none knows where others are dead and no information about the particular disease in question is forthcoming, others again fail to reply because they are care free and grudge the trouble The recognition of these things led to the foundation of the Mackenzie Institute in St Andrews What is certainly true is that clinical records would be made much more complete and often extremely valuable if more retired doctors retained sufficient interest in medicine to be curious about their one time patients Many of them have lived long enough for their records to have exceptional value But there are few men so remarkable in this respect as Prof Knaggs who since his retirement has published one of the most authoritative descriptive works on diseases of bone that we possess He belongs to that small band of men who retain their creative mental faculties as long as life lasts Sir Charles Ballance was another recent conspicuous instance Prof Knaggs is following great examples Metchnikoff did some of his greatest work after he was sixty Michael Angelo died in the height of his fame and ability at eighty nine and two years ago a former professor at the Slade School had his self portrait bought for the nation when he had passed his eightieth year Other instances will occur to many minds at once Difficult as it is to believe, it is true that the mental, inventive and artistically emotional faculties although they may not be capable of such sustained activity, may remain at their peak until very advanced life

THE ELECTROPHYSIOLOGY OF THE CORTEX

A monograph by Dr A E Kornmüller[1]—the first to appear on the electrophysiology of the cortex—is the complement to the classical histological researches of Oskar Vogt and his collaborators on the cyto architectonics of the cerebral hemispheres This fact gives it a special value and also exposes it to certain criticisms Vogt has devoted his life to producing evidence that the cortex of man and animals is divided into a score or more of well-defined ' fields distinguishable by their histological character and mostly also by the effects of stimulating them The greater part of this book consists of an attempt to show that in the rabbit and the ape these various fields are characterised also by their specific electrical discharges (Eigenströme) during comparative rest and by their electrical response to sensory stimulation.

Although the detail of Vogt s claims may still be a subject for controversy no one supposes that all parts of the cortex exhibit an identical structure, and it is certainly important to ascertain whether there is a variation in electrical properties corresponding with the undoubted histological differences The records now reproduced in this book purport to supply the evidence upon which the verdict must be based Technically they are excellent they were obtained by means of some of the most elegant machinery which has ever been used for the study of a biological problem specially designed and built by Tönnies for this work. Their interpretation however is a matter upon which opinions will differ In the main Dr Kornmüller is probably correct in asserting that the various parts of the cortex produce electrical discharges of different types but the records here submitted suggest as much variation in any one area from time to time as between different areas and this is disappointing to those who were quite willing to be convinced. Moreover it is tempting to wonder whether this preoccupation with local differences is at all likely to throw fresh light on the problem of the origin and significance of the electrical phenomena themselves notably on those observed in man which are only briefly mentioned.

There is nevertheless much valuable matter in this monograph, perhaps the most interesting to medical men being the study of the electrical discharges observed in the rabbit s cortex during the exhibition of convulsant drugs such as strychnine and mescaline. The convulsion waves produced by the local application of such drugs do not seem to spread far from the site of application and their character depends to some extent upon the area concerned less upon the nature of the convulsant Areas distant from that to which the drug is applied usually show a diminution of the specific resting discharge though Gozzano has shown that the symmetrical point in the opposite hemisphere may discharge synchronously with the abnormally stimulated point unless the corpus callosum is divided. The relation of the electrophysiological data to general theories of central nervous function is discussed perhaps prematurely It is difficult for example, to see what direct bearing Dr Kornmüller s hypothesis of specific electrical activity has on the question of whether the central nervous system acts "as a whole" or not, if indeed this is a pertinent question. The amplifier in neurophysiology has proved to be something of a Pandora's box; it has certainly released a number of awkward problems, but these are likely to be solved sooner by patient experimentation than by attempts to fit them into preconceived theories.

SUPPURATIVE TENOSYNOVITIS

THE treatment of tendon sheath infections of the hand is notoriously unsatisfactory and good results are uncommon. Dr. Robert Grinnell has reported[1] a detailed study of 125 cases of suppurative tenosynovitis that have been followed up for an average period of 16 months, thus making it possible to correlate the functional result with the method of treatment and with the various other factors. This contribution is the more important because definite facts about the results of suppurative tenosynovitis are hard to find, but if the treatment of this crippling condition is to be improved these must be studied. One of the defects of Kanavel's admirable book is the scanty information on this point. Nearly half Grinnell's cases were due to wounds at the finger flexion creases—chiefly at the distal crease. The most important of the other causes was infection of the distal closed space, which was the site of primary infection in 18 per cent. of the patients, thus proving the necessity for prompt and careful treatment of this very common type of whitlow.

The diagnosis of an uncomplicated case of tenosynovitis is fairly easy, but it is often very difficult to know when an infection elsewhere in the finger has invaded the tendon sheath. This is well illustrated in the series for the correct diagnosis was made in nearly 90 per cent. of the primary cases, but in only about 60 per cent. of the secondary cases. Though in 12 patients uninfected portions of a tendon sheath were opened owing to a wrong diagnosis, in 11 no apparent ill effects ensued. Grinnell considers that when reasonable suspicion of tenosynovitis is present it is far better to incise than to delay. A neglected sheath will give much greater disability than one opened unnecessarily. Generally the sheath was drained by the usual antero-lateral incision, the flexion creases being avoided. In a few cases, however, to provide freer drainage he used Auchincloss's method of exposing the sheath by dissecting up from in front of it a flap of skin and subcutaneous tissue with its base proximal, and the results were encouraging. Post-operative treatment is not described at any length, but it appears that the application of sterile dressings periodically moistened but not removed has better results than "hand soaks," by giving less opportunity for secondary infection to develop. Nothing is said about the stage at which passive and active movements were started.

Perhaps the most valuable data in the paper refer to the functional results, judged mainly by the mobility of the finger joints. There was no movement at the interphalangeal joints and little at the metacarpophalangeal in 35 per cent. of the cases; only 17 per cent. showed an almost complete return to normal function. The best results were obtained in the thumb—except when the ulnar bursa was secondarily involved, and the worst in the little finger. This is explained by the fact that the thumb has only one long tendon to become adherent, one less joint to become stiff, and many more small muscles to take over the functions of the long tendon. The little finger has in addition the great handicap that its sheath communicates with the ulnar bursa. It is noted that whereas spread of infection from radial to ulnar bursa was not uncommon, there was only one case of spread in the reverse direction. This has been reported by other observers and is difficult to explain. Grinnell attributes the poor results chiefly to late operation. The average duration of tenosynovitis before operation was 6.2 days, and the time factor was shown to be particularly important in the causation of tendon necrosis which occurred in more than half the cases. But even when the best treatment is given promptly results are often bad. "The last word," he concludes, "has obviously not been said as to the best type of incision, the best method of drainage, and the best post-operative treatment."

VOLUNTARY HOSPITAL FINANCE

ALTHOUGH the paper contributed by Mr. C. E. A. Bedwell, house governor of King's College Hospital, to the Medico-Legal Society early this year was primarily concerned with the legal status of voluntary hospitals, the full text, now available in the current issue of the *Medico-Legal and Criminological Review*, shows that it also provided material in relation to their financial position. In particular Mr. Bedwell directed attention to the analogy between the Local Government Act, 1929, and the Education Act, 1902. Under the latter many voluntary schools have ceased to exist and the system of education has gradually become more uniform in character. Moreover, directly the local authorities provided schools on any considerable scale the cost of education steadily increased and the difficulties of the voluntary schools grew in the same proportion. Exactly the same situation is confronting the voluntary hospitals. For the present, according to figures given by Sir Charles Harris in the *Times* of March 12th, the income of the voluntary hospitals is continuing to expand though that admittedly is not the same thing as keeping pace with the requirements of the population. The figures do not show to what extent additional income is being actually received from payments by local authorities. Sir Charles Harris advocates some form of rationalisation by which the voluntary hospitals "should abandon the traditional isolation of each unit in favour of progressive and well-organised team work." He looks to Lord Sankey's Commission to provide some solution of the problem while he cannot accept the suggestion of a previous correspondent of the *Times* that assistance might be given through a national committee instead of allowing the voluntary hospitals to be subjected to the pressure of local competition with its inevitable result. Even in London where the considerable resources of King Edward's Hospital Fund are available no special attempt has been made to maintain the voluntary system in an area of South London where it was practically non-existent until King's College Hospital was moved there in 1913. In spite of strenuous struggles it has remained incomplete, although additions have recently been made, so that the need for beds in that area became an issue in the recent election of the London County Council. Accordingly an L.C.C. institution within a short distance of K.C.H. has been developed into a hospital and another hospital is being built at Tooting. Thus the delay of the voluntary hospital authorities to pursue a united and considered policy is providing the opportunity for the local authorities to put their plans into operation The same thing is taking place all over the country, as can be seen by any diligent reader of the *Public Assistance Journal* which frequently publishes articles surveying their developments Sir Charles Harris deplores that an awakening did not take place more promptly on the passing of the Act of 1929 but even now the friends of voluntary hospitals do not seem to realise all that is happening around them.

---

SOCIAL CONDITIONS IN SOUTH WALES

FEW efforts have ever been made to collect and set forth in detail the social state of any country or district. Yet again and again historians are searching for such records of the past whence to obtain both the setting and explanation of the deeds of which they tell. An industrial survey of South Wales in three stout volumes[1] crowded with information concerning the life of the people on that great coal field, now in a state of depression, provides the sort of document which will be a permanent source of reference. As the story is told of how overseas trade has been hampered by international quotas subsidies and devaluations the interdependence of every part of the civilised world upon every other is brought forcibly to attention South Wales is profoundly affected by what is happening in France Germany Italy Japan or Polish Upper Silesia Import duties have injuriously affected the export of coal and a general resumption of foreign lending and a large measure of international free trade are needed to restore the coal exports of South Wales Even so mining still stands out first among the occupations accounting for 37 per cent of the workers—but it claimed over 50 per cent. in 1923 it employed 218 835 persons in 1924 but only 129 889 in 1934. The tinplate trade and iron and steel industries each find work for 5 per cent. and the distributive trades for some 12 per cent. Other important industries are few The district is geographically unique with a series of deep narrow valleys running parallel from the lowlands bordering upon the Severn sea in a northerly direction up into the mountains Each valley is cut off from its neighbours by intervening hills and is self contained. Each has come to be thickly populated by a mining community entirely dependent upon the collieries for its existence Communications are by road and rail down the valleys towards the sea upon which the coal is carried across the world. Such mining communities do not take readily to new forms of industry Yet necessity is a hard master; and an example may be sought from what occurred in the black country that great triangle bounded by Birmingham Wolverhampton Dudley and Stourbridge in the seventies and eighties of last century Then the great 30 foot seam of South Staffordshire coal was being worked out and the iron ore of the district was being exhausted The district left desolate but densely populated, with little work and worse prospects than to day face South Wales seemed doomed. Unfortunately no industrial survey was then made to enable the progress to be traced by which that black country far from the seaboard with no minerals and its only asset an unemployed population has become most prosperous turning out chemicals glass galvanised and enamelled ware bicycles motor-cars nails and bolts needles watches and jewellery This is a transformation at which South Wales may look and take courage For she has to her advantage still large reserves of ungot minerals and magnificent seaports over and beyond her most valuable commodity—her man power An interesting note is sounded by considering the trend of the population which, like that elsewhere in these isles promises to decline in the near future This decline in South Wales may be expected to amount to 79 000 males between ages 15 and 60 by 1943; so that the surplus of labour in the region which is placed to day at about 80 000 may be expected to have disappeared by that year without the introduction of new industries Special attention is due to the third volume of this valuable survey which points out what new activities could be advantageously developed in South Wales

NIGHT-BLINDNESS

HEMERALOPIA or night-blindness sometimes wrongly called nyctalopia, may be due to various intra-ocular diseases So called idiopathic or essential hemeralopia, which is by no means uncommon and which may be present in mild or moderate degree without the patient knowing it may, according to H Jeghers[1] be due to deficiency of vitamin A Vision in dim light depends upon the metabolism of visual purple in the retinal rod cells When the eye is exposed to bright light, the visual purple becomes exhausted but is rapidly regenerated if enough vitamin A is present in the body By various photometric means, night-blindness due to lack of vitamin A may be quantitatively measured. Thus Jeans and Lentmire found slight or moderate deficiency of vitamin A in 21 per cent. of a large group of children and in as many as 70 per cent. in other more extensive surveys Among adults both I C Park and Jeghers found similar deficiencies ranging from 10 per cent to 50 per cent. in various groups In almost every instance where they tried to do so these observers were able to bring the photometer reading to normal and cure the hemeralopia by giving vitamin A by mouth, or carotene, for two weeks or longer This association between night-blindness and lack of vitamin A is of practical importance, especially to motorists P Vignalou who in 1933 reported the case of a driver who had repeated motor accidents always at night and proved to have night-blindness, pointed out that the French laws ignore hemeralopia as a ground for refusing a driver's licence, and the same holds true for the laws of this country and the United States But not only motorists are concerned in this matter Aviators engine-drivers members of the fighting services and in our own profession radiologists who do fluoroscopies in darkened rooms, are other obvious examples of persons in whom night-blindness may be a dangerous disability The subject is certainly urgent enough to warrant the attention at least of those concerned with traffic problems

TUBERCULOSIS IN INFANCY

A SHORT but careful study of the mortality in a group of tuberculin positive infants is reported by Dr Miriam Bailey from the department of epidemiology of the Johns Hopkins University school of hygiene and public health and the department of pediatrics of the Johns Hopkins Hospital[2] 170 children of whom 72 were white and 98 coloured found to be infected with tuberculosis before reaching two years of age were kept under observation for periods ranging from one to five years In the first year after discovery of infection nearly 1 in 10 of the white children died and rather more than 1 in 5 of the coloured children In the following four years the mortality was very much lower, 3 4 per cent amongst the whites 9 6 per cent amongst the coloured, so that about 70 per cent of the total mortality experienced in the five year period occurred during the first year after infection was observed In every time interval the coloured children suffered a mortality more than twice that of the white children This higher rate appears to be attributable to their greater tendency to develop parenchymal lesions Once such involvement of the lung parenchyma has taken place there is no difference between the two races in fatality and nearly one third were dead within the first year, a figure which may be compared with the 7 per cent mortality of those who displayed no parenchymal lesion at initial X ray Clinical experience suggests that the younger the child the more unfavourable the prognosis, and this is borne out in this inquiry Children found to be infected before six months of age had a fatality rate of nearly 78 per cent within five years of the discovery of infection, those whose infection was found at 6–12 months of age had a rate of 18 per cent, and those at 12–24 months of 15 per cent Children with known intrafamilial sputum positive contacts showed a slightly higher mortality than children not known to have been exposed to infection

THE MARIE CURIE HOSPITAL

> " It was her hope and belief that the Medical Women's Federation might, as a corporate body with a large available amount of clinical material, institute some scheme of research under which individual members' work might be directed correlated and unified so as to yield more valuable results than might accrue from solitary effort "

THIS is a quotation from our report [1] of an address on cancer research given by Dr Helen Chambers to the London Association of the Medical Women's Federation on Feb 12th 1924 At the conclusion of her stimulating address the Association appointed a cancer research committee which initiated radium therapy clinics at four hospitals, in or near London, staffed by women doctors, a director of research coördinated the treatment given and followed up the results These were satisfactory from the start, but the inconvenience of having four centres as far apart as central London (2) Clapham, and Brighton, was so great that the bold decision was made in 1929 to found an ad hoc institution which is now the Marie Curie Hospital with 39 beds and the most modern X ray equipment in addition to an ample supply of radium Dr Chambers did the pathological work of the hospital until her death last year in cramped quarters and with minimal facilities And her own patient and careful examination of the material submitted no less than her unobtrusive service on the board of management and on committees, contributed much more towards the realisation of her dream of productive coördinated research than she herself ever realised It was fitting that the spacious new laboratories described in our last issue should have been named after her and that her friends should be given an opportunity to contribute towards their equipment as a memorial to her zeal and vision When Queen Mary visited the hospital on March 19th to declare the new block open Lord Dawson reminded the company of the fine results being obtained by the honorary medical staff working under Dr Elizabeth Hurdon as director of research—results which Dr Henri Coutard described later as " parmi les meilleurs du monde entier " Mlle Eve Curie by now a familiar friend at the hospital, added her tribute and her thanks for the successful development of her mother's life work on its humane as well as its scientific side Mrs Walter Runciman, chairman of the board of management, showed that nowadays there is much reason for hope and good cheer in a hospital chiefly concerned with the treatment of cancer, and it was on this optimistic note that the ceremonial part of the proceedings resolved into an informal gathering of those interested in various aspects of the hospital's work That this is of the first order is clear from the reports issued from time to time, it should soon be possible to present results over a ten year period and since efforts to secure an international acceptance of certain methods of keeping records have been successful these results will be available for comparison with the late results obtained at continental clinics We have every hope that the Marie Curie Hospital will continue to rank among the best

A CENTENARY APPEAL

THE decision to mark the Royal Medical Benevolent Fund's centenary with a special appeal has not had the success that it so clearly deserved Its purpose was to raise the Fund's annual income from £14 000 to £20 000, thus enabling the grants to distressed medical practitioners or their dependants to be substantially increased The report for 1936, given at the annual meeting on March 16th, shows that letters were sent to 44,694 members of the profession during the year, asking for new subscribers and for donations to the centenary fund, and accompanied by a historical record of the work of the Fund during the hundred years, compiled by Sir Humphry Rolleston This resulted in an addition of £3872—after costs amounting to £660 had been deducted—and 117 new subscribers The committee were not content with this and decided from past experience that the response might be bettered by a reminder, and a further 220 subscribers were enrolled from the London district This has encouraged the committee to extend this year the scope of the reminder to the rest of England, Scotland, and Wales The addition to the Fund has raised the annual income from subscriptions and donations by £510 to £12,671 A heartening feature of the appeal was the energy shown by helpers in various centres in organising social functions, which succeeded in producing over £400 On the other hand, the publicity given to the appeal was responsible for even more calls for help There were 136 new applicants which with the 220 annuitants brought the total of those who received financial aid during the year to 851, the sum given being £21 409 A request for donations at Christmas brought in £728 which allowed gifts of 30s to many of the more needy cases Though the appeal has so far been only partly successful in its original aim the response to the reminder in London encourages the hope that a further request to the rest of the country will greatly decrease the deficit Even the fact that an allowance of £40 a year to a medical man could be increased to £52 shows how important it is that the renewed efforts of the Fund's committee should be rewarded by the participation of every member of the profession Surely that is not too much to ask

PRINCIPLES OF MEDICAL STATISTICS

XIII—FURTHER FALLACIES AND DIFFICULTIES

Proportional Rates

It is not uncommon for some confusion to be shown over the difference between absolute and relative figures For instance, take the following figures for England and Wales in 1932

Age-group (years)	Estimated population in age-group	Number of deaths registered		Death rates per million	
		All causes	Tuberculosis (all forms)	All causes	Tuberculosis (all forms)
5–9	3 181 900	6601	774	20 5	243
10–14	3 349 100	4643	827	1386	247

From the estimated *populations* and the *numbers* of deaths registered the death rates experienced in the two age groups can be calculated At ages 5–9 the death rate from tuberculosis was 243 per million persons and at ages 10–14 it was 247 a negligible difference. *In other words the risk of dying from* tuberculosis did not vary materially in 1932 between these two age-groups Supposing however we had no means of estimating the populations exposed to risk and the sole information at our disposal consisted of the *deaths registered* from tuberculosis and from all causes In that event the only rate that it is possible to calculate is a proportional rate—i.e. the deaths from tuberculosis as a percentage of the deaths from all causes At ages 5–9 this rate is 774×100÷6601=11·7 per cent and at ages 10–14 it is 827×100÷4643=17·8 per cent The *proportional death rate* from tuberculosis is 52 per cent. higher at ages 10–14 than at ages 5–9 It is necessary to be quite clear on the meaning of this proportional rate The information it gives is that *in relation to other causes of death* mortality from tuberculosis is more frequent at ages 10–14 than at ages 5–9 This is certainly an important aspect of the figures it clearly shows that any action which reduces deaths from tuberculosis (without changing the death rate from other causes) will have more effect on the total death rate at ages 10–14 than at ages 5–9 *because more of the total deaths* are attributable to tuberculosis at the higher ages But obviously we cannot deduce from the proportional rates that the *absolute* risk of dying from tuberculosis differs in the same ratios; we have, in fact seen that the absolute risks are equal. The proportional rate is dependent upon the level of two factors—viz the deaths from tuberculosis and the deaths from all causes—which form the numerator and denominator of the ratio Differences in *either* factor will influence the ratio In the case cited the numerators (deaths from tuberculosis) are nearly equal 774 at ages 5–9 and 827 at ages 10–14 but the denominators (deaths *from all causes*) differ appreciably 6601 at 5–9 and 4643 at 10–14. The proportion of deaths due to tuberculosis at ages 10–14 is higher than the proportion at ages 5–9 not because of a rise in the incidence of tuberculosis but because there is a fall in the incidence of other causes of death While other causes of death—e g diphtheria scarlet fever measles—are declining tuberculosis remains nearly steady Relatively therefore its importance increases absolutely it is unchanged

Changes in Proportional Rates

To take another example in 1917 the deaths at age 0–1 year formed 12·9 per cent. of all the deaths registered in England and Wales whereas in 1918 the proportion was 10·5 per cent It does *not* follow that the infant mortality rate of 1918 was lower than that of 1917 in fact it was very slightly higher 97 per 1000 live births compared with 96 in 1917 The lower *proportion* in 1918 is due to the great increase in deaths *at ages over 1* as a result of the influenza pandemic The numerator of the ratio did not change appreciably (64 483 deaths under 1 in 1917 and 64,386 deaths in 1918) the denominator did change appreciably (from 498 922 deaths at all ages in 1917 to 611 861 deaths in 1918)

Similarly an absence of change in a proportional rate does not necessarily denote an absence of change in the absolute rate If in 1900 there were 5 per cent of all deaths due to cause X and in 1930 the proportion was still 5 per cent this is not incompatible with an absolute decline in the mortality due to cause X. If the death rates due to cause X and to all other causes have *both* been halved the proportion must remain the same

PROPORTIONAL DEATH RATES IN OCCUPATIONS

Correspondingly a higher proportion of deaths due to cause X amongst, say coal miners than amongst bank clerks does not necessarily denote an absolutely higher death rate from that cause amongst the former Expressing the numbers of deaths due to each various cause as *percentages of the total* number due to all causes gives a series of figures that must add up to 100 Differences between any one proportion amongst miners and bank clerks must to some extent influence all the other proportions. For instance, if the proportion of *deaths amongst miners* which is due to accidents is very much higher than the corresponding proportion amongst bank clerks it follows that other causes of deaths amongst miners must be *proportionately* decreased. The point is clear if we suppose only two causes *of death to exist* say accidents and tuberculosis Amongst populations of clerks and miners of equal size there are let us suppose, in the former 50 deaths of each kind while amongst miners there are 100 deaths from accidents and 50 deaths from tuberculosis The *actual* mortality rates from tuberculosis (to deaths divided by the number in the population) are identical for the *populations* are of equal size but proportionately the tuberculosis deaths form only one-third of the total amongst miners and one half amongst clerks. The relative excess of tuberculosis amongst clerks is not due to an absolutely greater risk of this disease but to a *lower risk from* accidents.

The cardinal rule in the interpretation of proportional rates is to pay equal attention to the numerator and to the denominator of the ratios Departure from that rule may be illustrated in one or two examples *culled from* published figures

PROPORTIONAL RATES IN HOSPITAL STATISTICS

In hospital statistics the population at risk—i.e from which the recorded cases are drawn—is usually not *known* Mortality or incidence rates cannot therefore be calculated and one falls back on proportional rates

For example cases of pernicious anæmia are expressed as a proportion of all cases of illness admitted to hospital the hospital being situated in the United States Of the 47 203 admissions of persons who were born in the United States 291, or 0 62 per cent , were cases of pernicious anæmia , of the 2814 admissions of persons who were born in England 25 were cases of pernicious anæmia or 0 89 per cent , and of the 7559 admissions of persons who were born in Russia 14 were cases of pernicious anæmia or 0 19 per cent It is impossible to accept these figures as adequate evidence of racial differences in the liability to pernicious anæmia The mortality from that disease is correlated both with age and with sex, the death rate rising with age and falling more heavily on women than on men There is no doubt that the incidence varies similarly The numerator of the proportional ratio (the number of cases of pernicious anæmia) is therefore influenced by the sex and age composition of the population from which the cases are drawn, and it is unlikely that the composition is the same in native born and immigrant populations

Equally the age and sex compositions of the populations at risk in the area may influence the admission rates for other causes of illness—i.e , the denominators of the ratios—since many causes of illness are correlated with age and sex In the absence of any knowledge of the constitution of those populations it is impossible to draw reliable conclusions from these different proportions of pernicious anæmia.

PROPORTIONAL RATES IN INFANCY

The infant mortality experienced at different stages of the first year of life was differentiated between urban and rural areas and gave the following figures —

Deaths per 1000 Live Births at Different Months of Age

—	Under 1 month	Months				Under 1 year
		1–	2–	3–	6–12	
Urban	29 67	12·06	8 73	22 77	22 14	95 37
Rural	23 77	7 44	5 18	10 98	11 29	58 66

Expressing these figures as proportions it is concluded that it is significant that while the proportion of infants succumbing in the first month after birth was 31 per cent in urban areas, it rose to 41 per cent in rural areas, which points to the lack of institutional facilities in connexion with confinements in such districts and to the difficulty often experienced of summoning skilled medical assistance in time " Clearly that conclusion does not necessarily follow from the proportions The *absolute* rate at under 1 month is *lower* in the rural areas than in the urban areas (23 77 to 29 67)—though possibly it might be lower still given better institutional facilities But it will remain *proportionately* higher just as long as the urban environment shows a relatively excessive death rate at ages 1–12 months If 69 per cent of the deaths are at ages 1–12 months in the urban areas and only 59 per cent in the rural areas, then whatever the absolute rates at age 0–1 month the proportions *must* be 31 in the urban and 41 in the rural areas at that age—i e , a *relatively* unfavourable state of affairs in the rural areas Given the best possible institutional facilities that state of affairs will prevail so long as the urban areas show higher rates during the remainder of the first year

From the absolute rates in fact two arguments may be advanced The smaller advantage in the rural areas at 0–1 month compared with later ages may be the result of inferior institutional facilities there, or it may be due to the fact that the urban environment does not exert its maximum unfavourable effects until after the age of one month

STATISTICS OF POST MORTEMS

Attention has been paid in recent years to the question as to whether cancer of the lung has increased The recorded mortality statistics have been regarded as unsatisfactory evidence, for the rise apparent in those figures may be due to more accurate certification of death now than in the past The number of post mortems at which this form of malignant disease is found is held to be a more certain and less changeable basis This number can be taken as the numerator of the rate But in the absence of a knowledge of the population from which the hospital draws its inmates, an incidence rate cannot be calculated In its place a proportional rate is used, taking, for instance, as the denominator either the total number of post-mortems carried out, or the total of all cases of disease admitted to the hospital. Thus we have the cases of cancer of the lung observed at post-mortem as a proportion of all post-mortems or of all cases admitted. Calculating this ratio year by year shows its secular trend In interpreting this trend we have to consider possible changes both in the numerator and the denominator The numerator, cases of cancer of the lung found at post mortems, may be influenced by an increasing interest in the condition , persons in whom it is now suspected may be more frequently submitted to post mortem than in past years If the denominator were unchanged this would give an apparently rising incidence But it is equally important to inquire whether the denominator has changed—i.e , all post mortems or all cases admitted If the criteria upon which post-mortem examination or admission to hospital are based have changed with time this will also inevitably influence the trend of the ratio An addition to the denominator of cases or post mortems that would not have been present in earlier years must result in a declining ratio, even though the actual incidence rate of cancer of the lung on the population exposed to risk has not changed

For example, suppose the incidence of cancer of the lung in the unknown population is 5 cases per annum, all of which come to the hospital, and are recognised, and this number is unchanged between 1900 and 1930 If in 1900 there were 500 post mortems carried out then the proportional rate is 5 in 500 , if in 1930 a laudable attempt to determine more accurately the causes of death of patients led to an increase of the post-mortem examination to 600, the ratio falls to 5 in 600, without any change in the real incidence

It may, perhaps, be reiterated that the denominator needs just as much consideration as the numerator

The Problem of Attributes

In medical statistics subdivisions of the cases treated have often to be made in order to ensure that like is being compared with like It is obviously idle to compare the fate of two groups of patients with cancer of the cervix uteri treated by different methods, if one group contains 50 per cent of persons whose disease was far advanced when treatment was begun and the other had but 10 per cent in the same category *To avoid this fallacy an attempt is made* to classify the patients according to the stage, or severity, of the disease when first seen Such a division, it is recognised, may be influenced by the different interpretation of what constitutes degrees of severity by the observers, and such statistics must always be regarded with that difficulty in mind

For instance, one hospital classifies two thirds of its patients to stages of disease 1 and 2 and one third to stages 3 and 4; another hospital has only one-quarter of the patients at stages 1 and 2 and three-quarters at stages 3 and 4 Do patients really present themselves at those hospitals in such widely differing proportions or is the difference due to differing standards of classification? The answer to that question is unknown but in comparing the fatality rates following treatment the problem must not be disregarded It must be remembered that different standards of classification may favourably influence one hospital as compared with another at *every* stage of the disease This may be shown diagrammatically by supposing the patients are set out in a line in order of severity from mildest to most severe

Hospital A   Stage 1 | Stage 2 | Stage 3 | Stage 4
Hospital B   Stage 1 | Stage 2 | Stage 3 | Stage 4

Hospital B includes in stage 1 a proportion of patients which Hospital A relegates to stage 2 the latter hospital therefore has only the very best of the patients in stage 1 and will in consequence have a more favourable result than Hospital B at that stage In the stage 2 group Hospital A includes favourable cases which B has called stage 1 while B includes less favourable cases which A classifies to stage 3 Hospital A will again show a better result The same difference is apparent in the subsequent stages Hospital B having only the extreme cases in stage 4 and A including some which B would relegate to stage 3 At each stage Hospital A will therefore compare favourably with Hospital B, though in the total there may be no difference whatever

In any series of statistics based upon division by attributes by different observers this possible fallacy must be considered with care The difficulty occurs acutely in the assessment of malnutrition amongst school children where different observers use different criteria of determination and place a different meaning on such terms as good fair poor &c The result has led in the past to an incidence that differs unbelievably from one place to another but so far no objective measure has been devised which will satisfactorily replace the subjective assessment In the same way differing interpretations by different persons made the statistics of the blind and dumb collected at the census enumerations in the past of little value and led to the questions being abandoned Faced with such statistics the reader must always ask himself Could these classifications have been made by means of objective measurements which given equal skill in making those measurements would not vary appreciably from observer to observer? If not how far may the presence of subjective influences affect the results and in what way?

SPECIAL ARTICLES

SILICOSIS AT HOME AND ABROAD

A PLEA for the extension of legislation in this country in respect of silicosis was made in a communication to the Medico Legal Society reported in our columns on March 6th. In this connexion it is of interest to review the progress in the gold mining industry in relation to the legislation for compensation for silicosis.

History of Legislation on the Rand

Gold was proved on the Rand in 1885 and mining started there in 1886 At first the mine workings were shallow and as the rock was relatively soft, friable, and damp the amount of dust was not excessive; but by the year 1802 extensive deep level mining was being done with an increasing use of drilling machines. In 1800 100 mines were working employing 12 000 whites and 100 000 coloured persons Before the Boer War very few people suspected that the mine dust was causing any injury to health The first warning was given by the Government mining engineer of the Transvaal Mines Department in 1902 when in his report he introduced the subject of the health of the workmen and mentioned miners' phthisis for the first time He stated that of 1377 machine men employed before the Boer War 225 were known to have died between October 1800 and January 1902 The attention of the Government was arrested by these facts and in December 1902 the first Transvaal Miners Phthisis Commission was appointed by Lord Milner to inquire into the incidence of the disease commonly known as miners phthisis

Regulations were made for improving the ventilation of the mines and these were supplemented from time to time by notices In 1907 the Mining Regulations Commission was appointed to revise and suggest amendments to the Regulations and a new code was issued in 1911 In the latter year compensation for miners phthisis was introduced for the first time in the Miners Phthisis Allowances Act to provide temporary relief to necessitous cases pending more extensive legislation Payment of compensation was made by the last employers who however could recover half the amount from the Government and a part of the remainder from a previous employer In 1912 an Act was passed which laid down a financial basis on a modified insurance method The benefits were financed by two funds—the Miners Phthisis Compensation Fund and the Miners Phthisis Insurance Fund The former provided benefits for the first 2 years *from* a fund which consisted mainly of quarterly levies on the scheduled mines and a contribution from the Government to make up any deficit up to a sum of £100 000 ("Scheduled mines were those wherein the mineral dust produced by mining operations was, in the opinion of the Minister of such a nature as to cause silicosis.) The insurance fund was for cases applying for benefit after August 1st 1914. It was financed by contributions from the mines and from the miners based on wages the mines contribution varying from 2½ per cent to 5 per cent the miners contribution being 2½ per cent The main reason for requiring workers to contribute apparently, was to secure their coöperation in preventive measures An amending Act was passed in 1914 extending the provisions for compensation to mine crusher house workers as well as miners and in certain circumstances to native labourers

An important Act passed in 1016 gave effect to the recommendations of a Select Committee appointed in 1915 Miners phthisis' and *silicosis* were now regarded as synonymous terms and a central medical bureau was established for dealing with all medical questions The Act prescribed periodical medical examinations at intervals of six months of white miners employed underground and suspension from work in the mines of any person found to have tuberculosis of the lungs.

A LANDMARK

The Miners Phthisis Act of 1010 repealed all previous Acts. It abolished workers contributions to the compensation fund and introduced differential rates of levy. The amount to be levied on an employer was assessed: (1) as to 45 per cent. on the amount of earnings of underground workers, (2) as to 35 per cent. on the silicosis rate of the mine, and (3) as to 20 per cent. on the assessment for income tax. The Act defined silicosis in three stages—ante primary, primary and secondary—and tuberculosis in two categories, i.e. open, as with T.B. in the sputum, or closed, but with seriously impaired working capacity.

The Miners' Phthisis Board appointed by the Government and consisting of a chairman and from three to six members with special knowledge or experience had extensive powers and duties of control and administration. The Board determined the amount of levy, granted benefits, reviewed awards periodically, and reported annually to Parliament. The medical bureau was appointed by the Minister of Mines and paid by the Government. Their duties included the conduct, direction, or control of all medical examinations required by the Act, including initial, periodical, and post-mortem examinations. Any miner could appeal against the result of a medical examination, in which case he was examined by three members of the bureau, and their decision was final.

In 1925 a consolidating and amending Act was introduced which is the present Act. It provides a right of appeal by a miner or his dependants from a decision of the bureau to the Medical Board of Appeal, consisting of three medical practitioners with special knowledge of respiratory diseases, whose decision is final. The Miners' Phthisis Amendment Act of 1934 introduces certain important changes to the consolidating Act of 1925. It follows the lines of certain provisions in the British legislation and amongst other things it provides that, in order to have a valid claim for benefits, a miner (1) must have worked underground in "scheduled" mines for a period amounting in the aggregate to 5 years, (2) must have worked for some portion of that period subsequent to August 1st, 1908, and (3) must submit a claim for benefits within 5 years from the date on which he last worked underground. These conditions do not apply to certain workers who have been resident in South Africa since the cessation of work in "scheduled" mines, or who have not worked in any occupation (other than a "scheduled" mine) which, in the opinion of the Board, is likely to have caused silicosis or aggravated the existing silicosis.

History of Legislation in this Country

If a brief outline of the legislation for compensation for silicosis in this country be studied, it will be seen that it has much in common with South African legislation. The two countries have adapted the same principles each to its own conditions, and have borrowed something from each other in the process.

The British Committee on Compensation for Industrial Diseases, 1906, explored the possibility of extending the Act to certain diseases of the respiratory system, including pulmonary fibrosis, and although they found that fibroid phthisis was a specific and sufficiently distinguishable trade disease, they found serious difficulties in the way of recommending its addition to the Schedule. These difficulties were: (1) the disease developed slowly and it would be troublesome to apportion liability amongst employers for an affected workman who had changed his employment; (2) the diagnosis from other respiratory affections was not easy; and (3) owing to the prolonged initial stage of the disease there would be a risk of some employers discharging workmen who developed symptoms. For these reasons the committee considered that it would be the more prudent course to keep in abeyance the question of scheduling the disease under the Act of 1906, but thought that it might be possible to devise special trade insurance schemes which would get over the difficulties. In 1911 the South African Miners' Phthisis Commission, after examining these findings, came to the conclusion that the difficulties were not so great in South Africa, where the disease developed more quickly, where white labour was scarce, and where there was a single industry in a limited area. Accordingly, legislation for compensation for silicosis was introduced in South Africa in 1912, seven years before it became operative in Britain.

Meantime advances were being made in diagnosis, and in 1917, in view of the continued occurrence of numerous cases of the disease in ganister mines, the Home Secretary decided that a special scheme of compensation should be worked out for the refractories industry, which consists of a special trade group engaged in getting and manipulating ganister and other highly siliceous materials for the manufacture of silica bricks and other articles used in the construction of furnaces. After negotiations with the employers and workers a scheme was agreed upon, and in order to give it effect the Workmen's Compensation (Silicosis) Act was passed in 1918. The Act enabled the Secretary of State to make schemes "for the payment of compensation by the employers of workmen in any specified industry or process or group of industries or processes involving exposure to silica dust" who were certified to have suffered death or total disablement from silicosis or silicosis accompanied by tuberculosis, or by reason of these diseases were suspended from employment. The Act provided for the establishment of a general compensation fund to which all employers in the industry were required to subscribe, and out of which all claims for compensation and all expenses should be paid. The liability was borne by the industry as a whole and not by individual employers; settlement of claims was by committees representative of employers and workmen, with an independent chairman; and all medical examinations were made by specially appointed medical officers.

A MEDICAL BOARD OF WHOLE-TIME OFFICERS

The Departmental Committee on Compensation for Silicosis dealing with the Refractories Industries (Silicosis) Scheme, 1919, examined the working of the scheme over the first four years during which it had been in force, and they made certain important recommendations. The medical officers appointed at the commencement of the scheme were generally the tuberculosis officers for the district in which the works were situated, with power to refer difficult cases to advisory committees or referees. (In South Africa, too, medical examinations were first carried out by a panel of local medical practitioners.) The committee recommended the establishment of a medical board of whole-time officers to make all medical examinations except certain initial examinations and to give all medical certificates under the scheme. Initial examinations were to be made of all persons entering the industry and periodical examinations of all workers at specified intervals. Persons found to be suffering from tuberculosis of the lungs were excluded from the industry. Compensation was not payable on account of tuberculosis unless it was accompanied by silicosis. (Compensation for tuberculosis alone was paid in South Africa on the ground of loss of employment resulting from suspension, through the desire of the industry to remove sources of infection from the mines.) The recommendations of the committee were adopted in August 1924 in an amendment to the Act of 1918 and a medical board of two whole-time officers with special experience of respiratory diseases was appointed following the lines of the Miners Phthisis Medical Bureau which was set up in South Africa in 1916 The Act of 1924 was replaced by Section 47 of the Workmen s Compensation Act 1925 A scheme was made in 1929 for the sandstone industry on similar lines to the Refractories Industries Scheme of 1925 providing for all medical examinations to be made and all certificates to be given by the Medical Board In addition schemes were made for the metal grinding industries in 1927 and for a large number of industries and processes classed as the Various Industries, in 1928 The machinery under these schemes was that applicable under the Workmen s Compensation Act to diseases scheduled under the Act—namely examination and certification by certifying factory surgeons The Departmental Committee on Medical Arrangements for the Diagnosis of Silicosis recommended in 1929 that all medical examinations should be made by the Medical Board and this was enacted in 1931 by a new scheme for medical arrangements which applied to existing schemes and to a new scheme for the asbestos industry To carry out the necessary work the medical board was increased to nine members

Compensation in cases where death or disablement is caused by silicosis or asbestosis or either of these diseases accompanied by tuberculosis contracted during employment is now payable in all industries where a serious risk of the disease is known to exist The number of new cases occurring year by year has increased during the last five years in spite of an improvement in the hygienic conditions of work owing to the extension of the Acts to more industries In 1930 there were 250 new disablement cases and 90 deaths in 1934 the corresponding figures were 415 and 138 These cases were spread over all the industries and processes to which the Acts apply Research is proceeding under the direction of a committee appointed by the Medical Research Council and in coöperation with industrial and scientific bodies with a view to extending the knowledge and understanding of pulmonary diseases due to the inhalation of dusts There is moreover a coordination between groups working in different parts of the Empire and in other countries towards this common end

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

THE SUMMER VACATION

Prof T K Monro gave an address last week to the students of St Mungo s College Glasgow at the close of the winter session He said that in spite of the progress made in the prevention diagnosis and treatment of disease by public health authorities and laboratory workers the general practitioner remains the first line of defence against disease and it is essential that his training should be as thorough as possible He referred to the long summer vacation of about three months during which little work is done by the students in Scotland There is a feeling that this is unnecessarily lengthy and that before long courses of clinical instruction will be organised during this period While this development seems both likely and desirable it is noteworthy that the present system of intensive clinical instruction that is carried out in the Scottish teaching hospitals throws considerable strain during the term on the clinical teachers Further these teachers have during vacation not only to take part in postgraduate courses of instruction but also to do extra work while their colleagues are on holiday

(FROM OUR OWN CORRESPONDENT)

HOW SHOULD DOCTORS TREAT EACH OTHER?

THE perennial problem of payment for services rendered by a doctor to his colleague and family has lately been revived by an exchange of opinions on this subject in the medical press According to Article 41 of the Code de Deontologie a doctor must not charge any fee to a colleague or his dependents or to a medical student, and special terms may be allowed members of allied professions This ruling is simple enough in theory But in practice neither the doctor who gives nor he who receives free treatment seems to be very happy about it Several alternatives have recently been put forward One is that the recipient of free treatment should pay the giver an appropriate fee to be earmarked for a third party such as some charitable institution for the widows and orphans of doctors but it is doubtful if this triangular arrangement would please anyone except the widows and orphans Another suggestion is that a doctor should charge his colleague only 30–50 per cent of his ordinary fee A third way out of the difficulty would be for doctors and their families to insure themselves against the costs of treatment The doctor treating them would then be paid by the insurance society and neither he nor his patient would be out of pocket This solution seems to be quite the most satisfactory in theory and in certain parts of France it has also proved satisfactory in practice In the course of the above mentioned correspondence a well known surgeon asks for a definition of the term a doctor's family To give point to his request he tells how a patient said to him before she paid his fee ' You forget, Doctor that I am the cousin of Dr X Dr Paul Boudin whose knowledge of the ethical and legal problems of French medicine must be unique or nearly so draws attention to the change which has come over the scenes since the above mentioned Article 41 was first drafted In the interval medical examinations have become highly specialised and tedious and treatment has become prolonged and varied Would it not therefore he suggests be well if Article 41 were to be remodelled to allow of fees being reduced by 50 per cent for those who formerly would have received examination and treatment for nothing?

INTRAVENOUS ANÆSTHESIA WITH SODIUM EVIPAN

At the naval hospital of Sainte-Anne which is under the direction of Prof P Solcard encouraging observations have been made of late on sodium evipan as a general anæsthetic administered by intravenous injection Dr Perves and Dr Badelon have given an account of their experiences in 48 cases and though they admit that the ideal anæsthetic is still to be found and that there is little chance of ever finding it sodium evipan given by intravenous injection constitutes in their opinion a definite advance in this field by virtue of its many good qualities Among them may be mentioned the speed with which general anæsthesia can thus be induced, and this is by no means a point to be neglected in the preparations for the next war when surgeons and anæsthetists can well count on being rushed One of the chief objections to intravenous anæsthesia with sodium evipan is the frequency with which it induces albuminuria Although the 48 patients operated on were young and healthy, as many as 14 developed albuminuria which in 4 cases was considerable Renal disease, even if it dates far back, seems therefore to be a contra indication to the use of this anæsthetic It should not be used on a person about whose antecedents little is known It is also not suitable in private practice as the violent excitement it may sometimes provoke would give much more trouble at home than in a hospital The contraindications also include advanced age, peritonitis, intestinal obstruction, septicæmia, severe hæmorrhage, cachexia and hepatic insufficiency On the other hand sodium evipan is admirable for the anxious, the pusillanimous the bronchitic, the tuberculous, and patients requiring operations on the face, neck, and thorax

HUNGARIAN ANTHROPOLOGY

AT the parterre of the Vienna Natural History Museum the results of the Hungarian anthropological excavations are exhibited The exhibition was arranged by Prof Lajos Bartucz At the opening ceremony Prof Lebzelter, director of the museum, said that the Hungarian soil is particularly good for the preservation of ancient bones This is the main reason for the fact that in Hungary anthropology is very advanced, but to this must also be added the exemplary organisation of the Hungarian National Museum, which renders possible a complete control of excavations In Austria, for instance, anything discovered becomes the property of the local museum, hence the material is wholly scattered and comparative research is almost entirely lacking Prof Bartucz has organised the Hungarian findings systematically and competently and he is able to supply 2000 skeletons with certain dates The Hungarian lowland has been not only part of the route of the ancient great migrations but also a stopping place and a refuge The Hungarian grave excavations in connexion with this race investigation work has had very interesting results Discoveries in a Hungarian cave now called the Mussolini cave prove that Neanderthal man also lived in Hungary In the Early Stone Age the country was inhabited by a dolichocephalic people but even this was not an entirely pure race In the Bronze Age (2000–1000 B C) the long skull gradually became more and more brachycephalic From the Iron Age only very few skeletons and skulls are left because at this time cremation became the vogue From about 1000 B C up to the time of the Romans western influences became more and more important, Germans and Celts mingled with the aborigines, stamping the race with their characteristics From the skulls it is established that in the Hungarians the German and western racial types appeared much earlier than the marks of Turkish Tartar influences The Huns were also connected with the Magyar race but findings are very few and even these are badly dated The quality of the Hungarian soil is such that while bones are well preserved, the jewels, clothes, and arms buried with the bodies very easily decay It thus favours racial but not ethnological research Prof Lebzelter said that there is no pure Magyar race It is in fact very mixed, and characters of many peoples may be found, but these when assembled in the race have produced a specific Hungarian type, just as in water oxygen and hydrogen do not retain their original properties From the racial point of view, he concluded, the Austrians stand nearer to the Magyars than to the Germans

INFLUENZA EXPERIMENTS

The great group of buildings of the National Public Health Institute here have expanded still further, for the Rockefeller Foundation have erected an influenza research institute, under the management of Dr Richard Taylor, delegated from England by the Rockefeller Institute to Budapest, to carry on the researches similar to those in Great Britain and in the United States

Dr Taylor's task is to try to discover an adequate protective method for the countries of Central Europe, in case a great pan epidemic like that of 1918 should return The Budapest influenza research institute works with quite different methods than was the rule, in general, against this common scourge of mankind He carries out his experiments on ferrets, but in Budapest experiments with protective inoculations are being made already in human beings It is still too early to speak about the results, but of 154 Budapest nurses who were given protective serum not one has contracted influenza Dr Taylor does not attribute any special importance to this, since this year the capital has not been visited by any such severe influenza epidemic as, for instance, that in England But it is a fact that the experimental animals are certainly protected by the inoculations for three to four months Immunity then gradually diminishes, but against slight infections it is still effective for several months From this Dr Taylor concludes that it may be possible to inoculate everybody at the approach of an influenza epidemic or, later on, even before each winter, which will protect them throughout the whole season On being asked about the lethal effect of ultra violet light as suggested by Brown and Wells in America, Dr Taylor says that he is sure that quartz light is able to kill the influenza virus, but whole cities cannot be protected in this way, as they can by an inoculation campaign

THE DEATH OF PROF DOLLINGER

One of the most prominent figures of the University of Budapest died last week in his 88th year In spite of his advanced age Prof Julius Dollinger was active almost up to his death He was an indefatigable worker, and as professor of operative surgery and director of the First Surgical Clinic of the University he has left behind a gap that will not easily be filled During the late war as surgeon general he organised the field surgery and erected the first permanent surgical hospital for war invalids He wrote a manual of surgery which has also been translated into German In medical public affairs he was very active, being at various times president of the Hungarian Surgical Society, the Royal Medical Society, and the National Medical Association

CORRESPONDENCE

ON THE TAKING OF CHILDREN S TEMPERATURES

To the Editor of THE LANCET

SIR —Dr Paterson s letter in your last issue begins with the very reasonable statement that there are three sites at which the infant s temperature can be taken—namely the mouth the axilla (or groin) and the rectum But with the clinical observations that follow it is not easy to agree The advantage of the rectal route is that an accurate reading is obtained in one minute compared with a doubtful reading obtained after even five minutes in the axilla. I say doubtful because unless a baby is very feeble or moribund it is something of a feat to keep a thermometer closely clasped in the axilla or groin for five minutes In a lively or restless baby the resulting reading is merely room temperature, modified to an extent which is determined largely by the skill and conscientiousness of the observer—deplorably variable factors

Dr Paterson says that diarrhœa can be provoked by regularly taking the rectal temperature merely from the mechanical action of a slim thermometer Is this a clinical impression or the result of observing a series of cases and controls? My own clinical impression is that only a baby who is already giving the matter of passing a motion his favourable consideration will be affected by the insertion of a thermometer in other circumstances he will scorn so mild a stimulus Moreover in those cases where an effective stimulus is regularly given (with a soap stick or rubber catheter) the end result is rather to produce constipation than diarrhœa As to taking the mouth temperature this is usually practicable in children over three If a stub ended thermometer is used, if it is held while in position and if any warning to the child about biting it is omitted the danger of breakage is negligible or non existent

Variation in temperature is the only manifestation of disease that we can accurately measure at the infant s bedside There seems to be no good reason for introducing an element of doubt into what should be an exact method of investigation

I am Sir yours faithfully

ERGOTAMINE TARTRATE IN MIGRAINE

To the Editor of THE LANCET

SIR —From a year's personal experience I feel I can say that we now have a drug of outstanding value in migraine. For over twenty years I had been subject to intermittent headaches which occurred once or twice a week almost always on awakening None of the usual analgesics gave any relief and exhaustive attempts to discover a cause proved unavailing No septic foci remained errors of refraction had been corrected and no biliary or intestinal cause could be found All forms of treatment tried, including both specific and non-specific desensitisation had failed At the end of September 1935 my attention was drawn to Bellergal (Sandoz) a preparation of the total alkaloids of belladonna with ergotamine tartrate and phenobarbitone which was said to have a regulating action on the autonomic nervous system and I began by taking one tablet three times a day The results were better than any I had had during the previous three years. The headaches were less frequent and less severe, and whereas they had hitherto lasted until the evening they usually now passed off between 10 A.M and 11 A.M. Because, however many authors have considered migraine attacks to be associated with disturbance of the sympathetic nervous system (acting through the neurovascular system of the brain) and because ergotamine tartrate one of the components of bellergal inhibits the sympathetic, I was induced to think that treatment with Femergin (ergotamine tartrate) might be more specifically indicated in my case Accordingly from Oct 24th 1935 I took two tablets of femergin by mouth each evening and one tablet each morning but it proved relatively ineffective and so did Bellafoline an inhibitor of the parasympathetic which is another component of bellergal indeed I think the bellafoline aggravated the trouble.

At this point I decided to test the effect of femergin by injection. I injected 0 75 c cm (0 375 mg ergotamine tartrate) intramuscularly and rested a short while within 45 minutes the headache was greatly improved, and in 1½ hours to my astonishment it had completely disappeared. Within about a month I had repeated the femergin injection on each of the five occasions that an obstinate headache developed and every time the headache cleared up in 1¼–1½ hours. It then occurred to me that it was possible that the femergin injections might be successfully used prophylactically For this purpose my plan has been to inject 0 5 c cm (a small dose) subcutaneously at bedtime on the eve of what I think may prove to be a very busy and strenuous day, and since I have done so many months *ago I* have always been able to procure absolute immunity for at least 24 hours, no matter how worrying a time I may have had. Throughout the whole period that I have been taking ergotamine tartrate either alone or as a component of bellergal, I have never experienced any unpleasant secondary effect other than a very occasional slight malaise after a femergin injection which however readily passed off

The relative efficacy of ergotamine tartrate by mouth and by injection seems to require further investigation. My early experiences with femergin orally had proved disappointing but as this was somewhat puzzling in view of the astonishingly successful results achieved with injections I have latterly been making further trials with oral treatment and have obtained much improved results with larger doses M E O Sullivan (*J Amer med Ass* 1936 107 1208) records complete relief of migraine attacks in 31 out of 45 patients given ergotamine tartrate by mouth and although the proportion of successes (69 per cent.) is not as high as she obtained with injections (92 per cent) oral treatment is clearly worth consideration, especially when it is inconvenient to give injections Another method of administration that I have employed is the sublingual which I have not seen mentioned elsewhere, though Von Storch approaches it in his suggestion of application of the liquid to the nasal mucous membrane. In my experience sublingual administration is far superior to ingestion and is indeed second only to injection I find that two tablets administered in this way are equal to five or six orally Prof. J H Burn has shown that in the cat only 30 per cent of ingested ergotamine is absorbed a fact that supports my experience of sublingual administration and I believe that this method will ultimately supersede the oral route.

From the outset of treatment I was anxious first about the possibility of acquiring tolerance to ergotamine tartrate, and secondly about the side effects of ergot—especially the former than the latter After several months' trial I ceased to worry, but I later had the good fortune of an introduction to Prof Rothlin of Basle, well known for his exhaustive research work into imbalance of the autonomic nervous system, and the effect of various drugs (including ergot) on imbalance, so I put the question to him His reply was that the risk of habituation is negligible and he cited the case of a doctor well known to him, a sufferer from migraine, who for over eighteen months had nightly given herself an injection of 1 c cm of femergin (0 5 mg of ergotamine tartrate) without any sign of habituation or any side effects He pointed out that, of course, the ordinary case would not require either so large a dose or anything like so frequent administration, and that consequently the risk of secondary effects was very slight, and that in any case intelligent supervision and temporary cessation of treatment would completely prevent them This coincides with my own experience of over a year's more or less regular administration in which I never felt the slightest ill effect, indeed, on the contrary, for some time after an injection I have often experienced a distinct sense of well being

Except for the very small proportion of cases in which a definite cause can be discovered and removed, the cure of migraine is as far distant as ever But, for the vast majority of patients who have to make the best of their affliction, we now have a drug that will relieve an attack, abort an attack, and prevent an attack. The darkened room and the narcotic sedative are things of the past

HORMONE TREATMENT OF UNDESCENDED TESTIS

To the Editor of THE LANCET

SIR,—Having just returned from abroad, this is the first opportunity I have had to reply to various points raised in letters commenting on my recent article in THE LANCET The points I wish to make are as follows —

1 A considerable proportion of cases of retained testis will descend spontaneously

2 Spontaneous descent occurs as development of the genitalia increases

3 Administration of gonadotropic hormones produces rapidly that increase in development which normally occurs gradually In this way descent of the retained testis may be obtained

4 Where genital development is considerable and a testis is undescended it is probable that retention is due to a mechanical cause This is the position in the majority of unilateral undescended testicles and in some bilateral cases

5 It is probable that successes with this treatment are obtained almost entirely in cases where spontaneous descent would ultimately occur

6 There is some experimental evidence that late testicular atrophy may follow the use of gonadotropic hormones The treatment has not been in use sufficiently long for this possibility to be excluded where patients are concerned

7 At present I think it is justifiable to use this method in bilateral cases with subnormal genital development

I agree with Dr Pearse Williams that the size of the genitalia varies considerably up to full puberty, but I consider that hormone therapy should only be employed where the genitalia are small in bilateral cases I should like to know more about the selection of cases employed by Drs Bishop and Hampson, their results (23 successes in 29 cases) suggest to me that they may not have excluded cases of retraction of the testis I am glad to have an opportunity of stating these points more clearly and trust that they may discourage the view held in some quarters that every case of imperfect descent of the testis is suitable for hormone therapy

I am, Sir, yours faithfully,
T W MIMPRISS

St Thomas's Hospital S E March 17th

ACCIDENT AND DIABETES MELLITUS

To the Editor of THE LANCET

SIR,—It is generally accepted that the reason why accidents cause an exacerbation of diabetes mellitus is that bruising of tissues leads to the production of a toxin which upsets the metabolism of diabetic subjects, just as they are upset by the toxins elaborated by some bacteria and viruses The object of this letter is to ask the assistance of the medical profession to answer the question whether accident can initiate diabetes mellitus in the same way as it is asserted that trauma can cause malignant disease or local tuberculosis A number of diabetic patients date the onset of their disease from an accident, but in only a small proportion of cases can previous glycosuria be excluded I should be very grateful to those who send me brief notes of patients who were free from glycosuria and the symptoms of diabetes mellitus before an accident and have developed glycosuria, with or without symptoms, following an accident however trivial. The records of the London Hospital furnish some cases but not sufficient to permit one to make a dogmatic statement

I am, Sir, yours faithfully,
O LEYTON

London Hospital E March 20th

DOCTORS' NOTEBOOKS OF LONG AGO

To the Editor of THE LANCET

SIR,—Your interesting annotation (p 702) on an old doctor's notebook tempts me to go one better Here is the first item, dated March ye 26th, 1688, in the notebook of a doctor at Cranbrook, Kent —

Mr Aston for the Itch			
A pot of oyntment lbss	0	2	6
for his arme aftar leting			
blud A Cattaplm	0	2	0
oyntment for ye itch	0	2	0
Pill Ext Rudii dr j	0	2	0
more oyntment	0	1	6
more oyntment	0	0	9
	0	10	9

Perhaps it was not "ye itch" after all or the ointment was not of the right sort since more than two pounds of it could not effect a cure

At the other end of the book the barber's side of the practice was entered Trimming was secured for a charge of from 1*s* 6*d* to 2*s* 6*d* a quarter There is no mention of the primitive urinalysis to which your annotation refers But we have here amongst our local records in the public library an interesting letter from one Abraham Heasman of Ticehurst, Sussex, who attained I fancy something more than local fame as a water doctor It is undated but on the back is a receipt for rates dated in 1729 The letter is addressed to a Mrs Bellingham who lived near Sevenoaks and it seems that Abraham was a ready rather than an accurate writer— I find by your waters you have boath of you and your son have fevers which your son hathe the jarndice with it verie much and lies in his head verie much and I think a kinde of surfit with it To spot the jaundice was not perhaps very clever but how he knew that it lay in the patient s head is difficult to surmise Nor was the water doctor any too sure for he writes "it was grate pittie you did not send a written noate of boath your conditions However treatment was duly prescribed in the simple words I have sent each of you a vomit and you be to take them boath. Detailed instructions follow— and everie time it works have 2 gallons of broath apiece radie and take it all if you can There is much more of interest in this letter which has the very wise post-script if you should have ocation to send again pray send this noate and then I shall be better knone what you have had of me

A country s doctor notebook commencing in 1688 is doubtless an unusual item Can anyone cap it with an earlier book ? There ought to be several earlier remaining

I am Sir yours faithfully

Sevenoaks Kent, March 19th GORDON WARD

HÆMORRHAGIC DISEASE OF THE NEW BORN

To the Editor of THE LANCET

SIR,—I have read with interest and profit Dr Norman B Capon s article in your issue of Feb 20th. It gives me the opportunity to mention a case that came to my care last year at the Colonial Hospital here in which bleeding came from the eyes as well as from the umbilicus

The history given by the midwife who attended the birth of the child was that blood had escaped continuously from both conjunctival sacs a few hours after birth accompanied by umbilical hæmorrhage The midwife brought the baby to hospital about 20 hours after its birth and I was called to see it 11 hours afterwards on account of the continued hæmorrhage from the eyes. The baby appeared quite healthy in every way and the history of the family was exceedingly good for both parents and several brothers and sisters I tried normal horse serum as an emergency measure and it had a beneficial effect for a short time both in its local action and by intramuscular injection. A blood transfusion was ordered but the baby died 34 hours after admission

Bleeding from the conjunctiva is not mentioned in Dr Capon s paper nor can I find any reference to it in the literature at my disposal here I have therefore written of this case because of the rarity of the source of bleeding and the fact that it was regarded as one for the ophthalmic department I understand that cases of this disease with bleeding from the rectum and genital passages are seen from time to time at the colonial hospitals in Trinidad

I am Sir yours faithfully

VIVIAN M MÉTIVIER.

Port of Spain, Trinidad B W I., March 10th

TURMERIC IN BILIARY DISEASES

To the Editor of THE LANCET

SIR,—Dr Oppenheimer in his interesting paper in your issue of March 13th refers to the use of turmeric in India for many centuries in the treatment of jaundice In The Magic Art Frazer has collected some descriptions of the methods used there They are not a bit like Dr Oppenheimer s For instance according to one technique the drug is applied externally from head to foot and three yellow birds—a parrot, a thrush, and a yellow wag tail—are tied by yellow string to the patient s bed In due course the mess of turmeric is washed off with water and the jaundice should then leave the sick man and pass to the birds The virtue of the turmeric of course rests in its curry powder yellow colour and it is interesting to note in this connexion that Dr Oppenheimer has found that the value of his preparation depends upon the yellow pigment curcumin only and not on any other constituent of the extracts from the herb

Turmeric is not the only yellow drug that has been used to treat the yellow jaundice Saffron podophyllum and dandelion are old folk medicines It is curious to see a remedy for long ages depending on the doctrine of signatures for its justification now supported by modern methods of investigation but it has happened before for the debt of therapeutics to folk medicine is considerable and your contributor s paper encourages the thought that further studies in the modern fashion of some of the old botanical remedies would be rewarded with results similar to his own I am Sir yours faithfully

Oxford March 9th EDWARD GALLOP

CHEST LEADS IN ELECTROCARDIOGRAPHY

To the Editor of THE LANCET

SIR,—All will agree with Dr Hill that a standardised method of obtaining the chest lead in clinical electrocardiography is urgently needed, To my mind there are very solid reasons for discarding the original American technique in favour of reproducing the chest lead curve in the manner advocated by Drs Willcox and Lovibond in your issue of Feb 27th, and Dr Hill s arguments do not convince me to the contrary

Two quite separate points have to be decided First the position of the electrodes on the body and secondly the manner of joining them to the galvanometer which determines the polarity Experimental direct leads purpose to record the variations in potential at a particular point on the heart and this involves the use of an exploring or dominant electrode applied directly to the heart and an indifferent electrode applied at some point distant from the heart. Though clinical chest leads are not strictly comparable with direct leads the same principle should be followed. Those who have used chest leads in clinical work will probably agree that the dominant electrode is best placed on or near the apex beat and the indifferent electrode on the right arm or left leg either of which is preferable to the back both on theoretical grounds and on grounds of expediency

The real difficulty arises over the question of polarity Drs Willcox and Lovibond advocate a reversal of the polarity employed in the original American curves so that the chest lead is as nearly as possible comparable with limb leads Anyone who has had much experience of chest leads in clinical work will readily appreciate the great convenience of reading the fourth lead *right way up* instead of upside down as necessitated by the American method

The custom in experimental work has been to so arrange the polarity in direct leads that relative negativity of the exploring electrode is represented in the finished curve as a deflection above the base line No less an authority on experimental electrocardiography than Dr F N Wilson comments on this custom as follows This practice is incon sistent with the well established conventions of coördinate geometry which demand that positive values of the variable be plotted above the time axis and negative values below it" ("Diseases of the Coronary Arteries and Cardiac Pain," New York, 1936) Again, Drs Kossmann and Johnston (*Amer Heart J* 1935, 10, 925), discussing the same subject, write as follows "the advantages of reversing the polarity of all direct, semidirect and præcordial leads are however, so great that we believe this policy will eventually be adopted by the majority"

As far as experimental curves are concerned, confusion would be avoided if all deflections were clearly designated by plus or minus signs to correspond with positivity or negativity respectively of the exploring electrode, as suggested by Wilson In clinical work I hope that British cardiologists will set an example in following the dictates of common sense, by reproducing the chest lead *right way up* in terms of accepted clinical standards They may feel fortified in so doing by the knowledge that they are also plotting positive values above the base line in accordance with scientific custom

I am, Sir, yours faithfully,
D Evan Bedford

ROYAL NAVAL VOLUNTEER RESERVE

Surg Lt S E Cooke to *Iron Duke*

Surg Sub Lts P H K Gray L Foster, and R F B Bennett promoted to Surg Lts

ROYAL ARMY MEDICAL CORPS

Lt C J O'Kelly resigns his short service commission.

REGULAR ARMY RESERVE OF OFFICERS

Maj Gen J S Gallie, C.B, C M G, D S O (late R A M C), Maj M P Leahy, and Capt A. W Bevis, having attained the age limit of liability to recall, cease to belong to the Res of Off

SUPPLEMENTARY RESERVE OF OFFICERS

D Thomson to be Lt

ARMY DENTAL CORPS

Short Service Commissions Lt J A O'Gorman to be Capt and W McGinnes to be Lt (on prob)

ROYAL AIR FORCE

Group Capt A E Panter to R A.F Station, Cranwell, for duty as Senior Medical Officer and Officer Commanding R.A F Hospital, Cranwell

Wing Comdr V R Smith to Headquarters, R A.F, Mediterranean, Malta, for duty as Principal Medical Officer

Flight Lts R F Wynroe to R A F Station Upper Heyford, and O S M Williams to R A F Station, Upwood

Flying Offr E B Harvey is promoted to the rank of Flight Lt

Flying Offrs E H E Cross to R A F Station, Hornchurch, and J R R Jenkins to R A F Station, Kai Tak, Hong Kong

Dental Branch—Flight Lts P M Margand to R A F Station, Gosport, and M J Pigott to R A F Depôt, Uxbridge

INDIAN MEDICAL SERVICE

Lt Col L Blake, M C, retires on account of ill health

Lt Col A J Lee retires

Indian Medical Department—Maj (Sen Asst Surg) J S Salt and Lt (Sen Asst Surg) H J C Flanagan retire

DEATHS IN THE SERVICES

Colonel Harry Arthur Leonard Howell, C M G, late R A M C, who died on Feb 26th at Lincoln in his 70th year was the son of Major R Howell of Sandgate He was educated at Manchester School and Queen's College, Cork, qualified L R C P Edin in 1892, and joined the Army in 1895, retiring in 1921 with the rank of colonel He served with the Tirah Expedition (1897–98), and on plague duty (1899–1900) when he was highly commended for his work in Bombay In the European war he was A.D M S, 1st Army, Central Force, and as officer in charge of R A.M C records he edited the "Roll of Commissioned Officers in the Medical Service of the British Army," published in 1917 at the University Press, Aberdeen He was editor of the *Gibraltar Chronicle* from 1907–10, and wrote several biographies which appeared in the *Journal* of the R A.M C In 1901 he won the Parkes memorial gold medal and prize for an essay on the prevalence and prevention of venereal diseases in the Army He was created C M G in 1919 His leisure time was devoted to historical research and to painting both in oils and water-colour In 1897 he married Adelaide, the daughter of Edmund Burke Brown J P, of Castle Park, Co Clare

Colonel Philip James Lumsden late I M.S, who died on Feb 27th at Fleet, Hants, was eldest son of John James Foote Lumsden, of Aberdeen He was educated at Aberdeen and Edinburgh, qualified M B, C M Aberd in 1886, and joined the I M S two years later At first residency surgeon in the Persian Gulf, he was later agency surgeon in Haraoti and Tonk, Kotah and Jhallawar, Quetta, and medical officer of the 44th Merwara Infantry at Ajmer From October, 1914 he was on military duty, and he retired in 1920

Colonel Ferberd Richard Buswell, C M G, late R A M C who died on March 13th at Kensington, was born at Brixton in 1864 and qualified M.R C S in 1887 taking house appointments at the Middlesex Hospital In 1893 he entered the Army as surgeon lieutenant, becoming major in 1904, and temp colonel whilst A D M S of a division in November 1915 He served in China in 1900 (medal) and during the European war when he was mentioned in dispatches and awarded the C M G in 1917

OBITUARY

ROBERT GORDON McKERRON M.D Aberd

The death occurred in Edinburgh suddenly on Sunday last of Dr Robert McKerron, emeritus professor of midwifery in the University of Aberdeen He had come to Edinburgh as was his wont to see the Calcutta Cup match, but became suddenly ill on the night previous to the match and died thirty six hours later

Robert was the eldest son of the late Rev Robert McKerron, and received his medical training at the University of Aberdeen where he graduated in arts with honours in 1884, proceeding to the medical degrees of M B C.M in 1888 He was a distinguished student in the university and early after graduation acted as assistant to the professor of physiology He became later gynæcologist at the Royal Infirmary Aberdeen and physician to the Royal Hospital for Sick Children in the city and was finally appointed regius professor of midwifery We have received the following brief obituary notice in which his high *position in the profession his success with his students* and his keen interest in sport are set out —

Not only Aberdeen and the north east of Scotland but a very large number of medical practitioners throughout the country will mourn the sudden death of Prof R G McKerron in Edinburgh on March 21st the night *previous to the international football* match at which he hoped to be present

Prof McKerron could be described as a real enthusiast in all that he did or was interested in whether it were work or play He was a keen teacher who was devoted to his students and they in their turn made of him one of the most popular of all Aberdeen professors He was an illuminating teacher of midwifery this he taught in the practical way which he considered would be of the greatest use later to the general practitioner as he always looked upon his class as potential general practitioners and not as is sometimes done at present as embryo specialists. He was an obstetrician of the old school who had little use for Cæsarean section unless it was absolutely necessary and under his care and deft manipulations this necessity seldom arose a fact that speaks adequately for his great obstetric acumen and skill. It was a pleasure and an education to see him deal with a difficult occipito posterior position or a placenta prævia

He was equally enthusiastic on games and was in his day a great cricketer In winter he followed Rugby football most keenly and rarely missed a Saturday match, no matter what kind of day it was in summer he turned his affection to the Aberdeenshire Cricket Club and was an equally enthusiastic supporter of the game He rarely missed his weekly golf match winter or summer and was a most competent bridge player No wonder that he was popular with all both young and old as he had interests in common with both *and a very large circle* of friends will miss him greatly

"Great sympathy is felt for his widow and for his three daughters and two sons one of whom is a professor of law in Johannesburg

BERNARD SCOTT M.R.C S Eng L S.A

Dr Bernard Scott whose death was announced on March 12th at the age of 78 was born in Brighton where his father was in practice as a doctor He went to Guy s Hospital at the age of 16 and qualified from that hospital in 1881 He held appointments at the Helen Bridge Hospital for Hip Diseases and at the West Sussex County Hospital Brighton and in the year 1884 went into practice in Bournemouth with his elder brother Dr T Bodley Scott In 1886 he married Lydia Margaret Whitworth of Windermere He rapidly acquired a reputation as a surgeon, and in 1892 he became honorary surgeon at the Poole road Hospital While following a very busy life as a general practitioner he found time regularly to return to Guy s in order to learn the technique of aseptic surgery which was entirely new since he had qualified and for many years he spent a fortnight of his summer holiday watching surgery at that hospital. He led an immensely active life and yet never appeared to be in a hurry and was left quite unruffled by the manifold irritations of the doctor s life He was both loved and respected by members of his own profession with whom he always worked with complete harmony

His favourite hobby was dry fly trout fishing and for many years every summer holiday was spent in this pursuit It was only last summer after he had succumbed to a severe chill whilst fishing on a bitterly cold day that he decided to give up practice altogether

He is survived by his wife and nine children two of whom have followed in his own profession while another is Elisabeth Scott, the well known architect

JOSEPH TREGELLES FOX M.R C S

Dr Tregelles Fox was born at Stoke Newington in 1855 the fifth son of *Joseph John Fox* surgeon. Like all his brothers he studied at the London Hospital under the constellation which included Hughlings Jackson Jonathan Hutchinson Andrew Clark, and Henry Gawen Sutton He had early interested himself in medical religious efforts such as Dr John Dixon s work for the Jews and Dr Pennefather's at Mildmay In 1880 he qualified M.R C S and L S.A. and went out as a medical missionary under the Friends Association to Madagascar Here he remained for seven years, working for two years single handed in a wide field including the organisation of a hospital and training selected native students His large collection of vesical calculi still exists. In 1882 he was joined by the late Dr William Wilson also a Friend who gave him much assistance in establishing a medical mission academy' and to whom he owed his life when seized with illness on one of their journeys This beginning of medical teaching in Madagascar was jointly supported by the Friends and Norwegian Missions and the London Missionary Society In 1886 Dr Fox was able to open a systematic course of medical studies and in the following year his 'Lessons in General Anatomy and Physiology Vol. I was printed in the Malagasy language at Faravohitra and became the text-book of the school It is illustrated with more than 100 reproductions of his original drawings which show his ingenious and uncommon turn of mind Ten years later when the French occupied Madagascar this academy became the Government hospital and medical school At that time 30 native students had passed through the course and qualifying examination and were doing excellent work all over the island

He returned to England in weakened health in 1887 and settled at Strathpeffer Spa where for a number of years he devoted himself to hydrological and climatic studies and the establishment of a mineral waters hospital Later, he removed for a further period to Leeds and followed his son to America practising in various parts of Oregon maintaining a strong interest in natural waters and making occasional contributions to the *Archives of Medical Hydrology*

Tregelles Fox was short of stature, an optimist by conviction, full of energy and resource, at times perhaps showing a *nimia diligentia* but never indolence, and he is still remembered by old patients with gratitude and affection He died at San Diego under the care of his son, Joseph Sanger Fox, on Jan 4th, 1937

PERCY LONSDALE McALL, M B , Ch B Edin

Dr Percy McAll, who died in Edinburgh on March 8th at the age of 66, served the London Missionary Society for 37 years in China Born in Leeds in 1870, he was educated at the Bristol Grammar School and St Olaves, Southwark From there he went to Cambridge and graduated in arts, proceeding later to Edinburgh and obtaining the degrees of M B , Ch B in 1898 He started immediately upon his missionary labours sailing the same year for China He was at first engaged on work in Wuchang and Hankow and while engaged in appointments at the hospital and medical school at Hankow, began to add the translation of medical text-books to his duties He thus made an important contribution to the training of Chinese doctors , indeed, he was largely responsible for standardising the medical vocabulary of China In 1918 he joined the staff of the medical school of Shantung Christian University at Tsinan (now known as Cheeloo), and two years later, in connexion with the translation department of the medical school, he rendered many important works on clinical pathology, bacteriology, and pathology into Chinese In 1924 a Chinese physician, Dr C L Kao, undertook the heavy task of translating the British Pharmacopœia into Chinese This work was carried on under the auspices of the British Chamber of Commerce of Shanghai, and the subsequent work of revising the translation was done under the direction of Dr McAll

Dr McAll was twice married His first wife, formerly Miss Winifred Bateman whom he married at Hankow in 1899 died at Wuchang less than two years later In 1905 he married Miss Lilian Mary Joyce a missionary who was nursing at the Hankow Hospital Dr McAll retired in 1935 and he and his wife who survives him made their home in Edinburgh Their son, Dr Kenneth McAll, is following his father's footsteps and proceeding to China as a medical missionary of the London Missionary Society

JOHN LLOYD DAVIES, M R C S Eng , L R C P Lond

Dr J Lloyd Davies whose death occurred on March 16th was a well known Newport citizen The son of the late manager of the Marshfield Iron and Tin Works he spent some time at Llanelly before entering the medical school of University College Hospital He took the English double diplomas in 1893 and was then for five years medical officer to the Dowlais Iron Company He was then appointed medical officer and public vaccinator to the Ludlow union after which he started in general practice at Newport where he soon came to hold several public appointments He took real interest in municipal affairs and was elected to the town council of Newport in 1902 He was Mayor of the borough at the outbreak of war, and met with great energy the responsibilities that fell upon him , in particular he was active in the reception of Belgian refugees, for which service he received the King Albert medal He was a J P for the county of Monmouthshire, and was elected an alderman of the borough His career of active practice was marked always by his devotion to public affairs, especially by his connexion with education He was chairman of the Newport educational committee for more than 20 years, and was the first chairman of the Newport insurance committee, having been the first doctor to be placed on the panel under the Insurance Act He represented Newport on the board of governors of University College South Wales, and for his services to his borough was made an honorary freeman He was 65 years of age at the time of his death

HENRY CHARLES ROBERTS, M B Liverp

We owe the following appreciation of the late Dr Roberts, who died on March 15th, to the personal knowledge of one of his friends and colleagues —

“The death of Henry Charles Roberts in his forty fourth year has robbed our little corner of Cheshire, and indeed Merseyside, of one whom to know was to love He qualified in 1916 and served in Mesopotamia After practising for a short time in Liverpool he came to Moreton He was a naturally gifted mechanic, and early became interested in anæsthetics He designed and made with his own hands a portable gas oxygen ether apparatus, a modification of what he thought best in the American Foregger and Heidbrink machines Latterly he had much improved this, and when the Cunard White Star liner *Queen Mary* was being equipped his apparatus was installed in her To those of us, his colleagues, who were willing to learn, he freely and generously gave of his special knowledge, and made clearly plain what others seemed to have kept a mystery, and this with undoubted financial loss to himself

“As anæsthetist to the Liverpool Dental Hospital, I believe it is true to say that he revolutionised dental anæsthetics there, and his lectures, with cinematograph films of dental anæsthesia, were becoming increasingly sought after He was skilled in all forms of his art, including evipan, avertin, ethylene, and cyclopropane, and at the time of his death was engaged on simplifying and making more economical the use of the latter He was an accomplished musician, photographer, and a keen student of nature delighting especially in his garden, and I shall always picture him coming to my poorly gardened house, his arms filled with flowers His never failing cheerfulness, generosity, and unassuming kindliness had meant so much that his unexpected death has caused real grief to his professional colleagues friends, and patients, and, among these latter the poor, who may have been said to worship him

“He leaves a widow and one son, to both of whom he was deeply devoted ”

W G McA

Hospital for Sick Children Great Ormond-street —On March 17th the Princess Royal president of this hospital, laid the foundation stone of the main block of the new hospital This is the beginning of the second part of the rebuilding scheme The first, the new nurses' home is almost completed The new block will cost £240 000 and the maximum number of cots in a ward will be 6 instead of 20 as at present Isolation glass partitioned cubicles will be attached to each ward, and oxygen will be laid on to every bed

Under this heading appear week by week the unfettered thoughts of doctors in various occupations Each contributor is responsible for the section for a month his name can be seen later in the half yearly index

BY A ROVER

IV

LOOKING at the germ diseases over which we still have practically no control they are probably nearly all of them the result of infection of the body by a special type of microbe which we call a virus Filtrable viruses they are sometimes termed because the infecting agent passes through the finest filter available This infective material has been proved to contain extremely minute particles the name elementary bodies is given to them We owe the first description of these particles to a Scot named John Brown Buist, who found them in the calf lymph used for small pox vaccination and also in material removed from small pox pustules After the delay that so often follows original observations like these a number of other workers have studied these Buist bodies and have confirmed their presence and importance British bacteriologists have been amongst the foremost in these researches and in particular Dr Mervyn Gordon and Sir John Ledingham

There is a lot of evidence for regarding virus bodies as being the cause of influenza encephalitis lethargica (or sleepy sickness) infantile palsy mumps measles and also (some would add) the common cold

* * *

The first appearance of that form of inflammation of the brain called encephalitis lethargica is quite uncertain because in the severe cases of influenza cerebral symptoms have often appeared causing confusion in diagnosis But serious outbreaks have occurred in the present generation as well as many sporadic cases The number of cases in which the brain symptoms appear the fever having been overlooked or absent altogether is probably still under-estimated The same applies to influenza nerve symptoms though these are of course less serious Acute poliomyelitis better known by its trivial name infantile palsy has close affinities with encephalitis It is a very old disease There is authentic evidence that it existed in Egyptian days and it is probable that encephalitis did also

* * *

What is equally or even more important there is a growing belief that the mystery of cancer a disease which equally lacks control in the true sense of the word may find part of its solution in the discovery of specific virus bodies That cancer is a microbic disease becomes more and more a convincing hypothesis as intensive research into its problems continues It is not difficult to visualise these minute virus bodies—each one is from five to ten times smaller than the ordinary micrococci settling like so much dust inside the very substance of the cells of an organ successfully colonising there (successfully that is from their own point of view) and thoroughly disorganising the cell economy The life of the cell continues—it is not killed—but it is stimulated (irritated) into that state of chaotic overgrowth which is the very essence of cancer I do not know of any problem connected with cancer as a disease which is not capable of explanation upon the basis of a hypothesis like that We shall see if we continue to be patient and painstaking and work with some vision if this be the truth or not

It is often held that the incidence of cancer has increased during the past fifty years This is very difficult to prove Several possible fallacies come into the argument especially improved diagnosis and better methods of registration Cancer is a disease of the second half of life indeed to a large extent it is a disease of old age An increase in the number of cases of cancer may therefore be no more than a confirmation of what we know already—that the expectation of life has risen by 15 years during the past two generations Old age brings not only its own infirmities but also its own diseases Senility is itself a disease and it is on the increase If we go on as we are going a man who writes in your columns in sixty years time will probably stress senility as being one of the most striking of the new diseases

It seems to me that certain generalisations emerge from this discussion of old and new diseases There has certainly been a swing over as it were from those frequent and devastating gusts of acute and virulent germ diseases to more insidious and chronic maladies. Life was very precarious in Elizabethan days and in the centuries immediately preceding and following them We must remember that what we know to-day about those terrible scourges refers only to the big epidemics there must have been thousands of what are called sporadic cases and there were places where some of these pests made themselves endemic So that in addition to the big waves of fevers that brought death in great swathes there was the steady constant loss of life in these other ways Sydenham estimated that in his day fever accounted for 70 per cent of the whole of medical practice To-day this figure is not more than 10 per cent.

* * *

The Elizabethan was very alive to-day and very dead to morrow If we exclude influenza which still seems to possess something elemental in its potentialities—that is judging by 1918–19 rather than by the mild epidemic we have just experienced—there are no diseases nowadays that spell violence as diseases did in Sydenham's time Unless we call venturing upon the streets and roads a disease Or war; which is, after all, the greatest of all modern diseases though it is a disease of the mind and not of the body It has existed since the race began but its casualties were formerly trivial by comparison with those due to disease To-day the proportions are reversed The Great War cost us over 700 000 lives and 2¼ million total casualties At the beginning of 1920 there were just over 1 million war pensioners and even in March of 1936 there were 400 000 permanent pensions being paid Of these 40 000 were on account of mental and nervous diseases Science has reduced enormously the casualties due to the attack of the microbe upon man but science has increased in much greater proportion the casualties due to the attack of man upon man

Then again the question arises what of the integral staff of our bodies and of our minds? It looks as though our enemies have become the men of our own house, rather than those who have got entrance from without Why is this? Has something gone wrong with the control? Or, to change the metaphor, are we discharging the battery at too high, and charging it at too low, an amperage? *Why* are we becoming the preys of our own saprophytes? *Why* is the tubing of our blood vessels and why are the working parts of the pump wearing so badly? These questions cannot yet be answered

* * *

We are living longer, that is one of the most striking results of the past fifty years of hard but intelligent work on the part of those who have inspired and administered our public health services Does someone ask *cui bono?* Why live longer if we cannot live more healthy and more happily? For it certainly does look as though, for many of us, our lives become "thin spun" long before the "abhorred shears" are due—so why take such pains to prolong them? Is our meticulous care of our shadowy present worth it? Is it worth suggesting security to ourselves in a gas mask and an (alleged) bomb proof cellar? But surely the answer is with us who do the living? How *long* a man lives depends upon his ancestors and the state of the public hygiene How *healthily* and how *happily* he lives depends upon himself Also be it observed that mere absence of disease is not enough Therefore we welcome an attempt by the State to organise the national physique

And later, but I trust not too late, perhaps we might do something to organise the national mind And so get back some of the *zest* for living that we seem to have lost, and the ability to enjoy this immunity from disease that we have accumulated

*** *Next month A Taddygaddy will be responsible for these columns*—ED L

PANEL AND CONTRACT PRACTICE

Suggested Amendment of Regulations

FROM the *Bulletin* of the Glasgow burgh panel committee we learn that the Scottish Association of Insurance Committees is suggesting amendments to the medical benefit regulations in the following particulars —

1 That a medical partnership might be allowed to have a list of patients (instead of the individual partners)

2 To prohibit medical superintendents of hospitals accepting patients for treatment in the hospital under national health insurance

3 To restore to insured persons unrestricted freedom of change of doctor

4 To provide, in the case of an investigation by the medical service subcommittee, that no person shall be assisted by "counsel, solicitor, or other professional agent"

5 To confer upon insurance committees a right of entry for purpose of inspection of insurance practitioners, surgery and waiting room accommodation

6 To oppose the representations which have been made to the Department of Health for Scotland for a national capitation rate instead of an areal one

7 To make it clear that committees have the right to refuse application by a doctor to join the medical list if, in the opinion of the committee, it is not practicable —e g, on account of distance—for him to give a proper service the doctor to have the right of appeal to the department

8 To provide that, in the case of a transfer of practice, the doctors pay the whole expense of issue of notices to insured persons

9 To relieve practitioners of responsibility for treatment in a hospital of a person admitted thereto for treatment

10 To ensure that under "acceptance of fees" nothing shall preclude acceptance by a practitioner of fees under Road Traffic Act

11 To make it necessary for a practitioner to obtain the consent of the committee to his absence for more than one month

12 To give a patient who is being treated by a partner the right to require the personal services of the practitioner in whose list he is included

It seems to us unlikely that insurance practitioners will welcome all these proposals The suggestion that they should bear the whole expense of notifying patients of transfers of practice will certainly be opposed Regulation 34 provides that the medical service subcommittee may if they think fit, permit any person concerned in an investigation to be assisted in the presentation of his case by some other person, provided that no person shall be entitled to appear in the capacity of counsel, solicitor, or other paid advocate It is not clear that the secretary of a panel committee might not be regarded as a professional agent Proposals numbered one and twelve appear to be mutually exclusive Practitioners will no doubt object to a right of surgery inspection being conferred upon insurance committees, if any visitation is necessary it should be made jointly, as at present, by representatives of the panel committee and of the insurance committee

Medical Mortgages A Correction

A note appearing in this column on Feb 13th referred to a case in which a firm of solicitors complained to an insurance committee Their complaint, in effect, was that, although the committee was aware of the mortgage of the practice and had, in fact, been paying the panel fees pursuant to the mortgage to other than the practitioner, it had without notice to their clients allowed something to happen to their clients' prejudice We now learn that the mortgage in question was arranged, not by a firm of moneylenders, as stated, but through the scheme for assisting medical practitioners sponsored by the Medical Practitioners' Union Our note, therefore, contained a misstatement of fact, which we regret, and the *misapprehension* led us *into an* implied criticism that certainly would not have been made if we had been aware of the standing of the parties We are informed that the matter was promptly adjusted through the borrower's solicitors and before our note was published, and that the insurance committee was immediately advised of the fact

A Disputed Point in Emergency Treatment

An insurance practitioner Dr A, on visiting one of his bedrid insured patients decided that he should be removed to an institution He arranged accordingly through the public assistance official, and in due course a nurse was sent, but upon arrival at the patient's bedside she doubted whether the patient was fit to be removed to hospital She therefore requested a visit by Dr A in order that he might clear her mind of the doubt as to the patient's fitness to be removed Dr A not being available, the nurse obtained the advice of

Dr B, another local insurance practitioner, who expressed the opinion that the patient was unfit to be removed from his home Dr B rendered an account against the public assistance committee for a home visit to the case on the ground that the service rendered was for and on behalf of that committee It was decided eventually that the assistance committee were not required to pay the account; the matter was one for settlement by the insurance committee since the advice called for and given was in the best interests of the insured person and, as such, was covered by the regulations and terms of service This decision seems to be the right one The second practitioner was called in not so much for the purpose of giving treatment as to certify the condition of the patient, and there is no doubt that it would have been the duty of the responsible practitioner had he been available to comply with the nurse s request for his services on behalf of an insured person

PUBLIC HEALTH

A National Health Campaign

The Central Council for Health Education has been invited by the Ministry of Health and the Board of Education to coöperate in a national campaign to increase the use of the health services At the back of the suggestion is the experience that antenatal clinics welfare centres and opportunities for dental treatment are not made use of to their full capacity and that a well thought out central publicity scheme combined with local personal interest might soon make the health services better known and more widely attended The campaign would start in October on general lines with the sympathetic interest it is hoped of the press and the B B C In the following months effort would be concentrated on particular services maternity and child welfare in November and December home and school in January social hygiene and tuberculosis in February and March The principal cost of the campaign will be borne by the Government but it is expected that every locality will add local colour to the posters folders bookmarks or whatnot by overprinting on them matters of local interest A schedule has been sent out to clerks of councils and medical officers of health asking for some idea of the quantities which could be distributed during each section of the campaign Reply is requested before April 14th to the secretary of the Central Council for Health Education, 1 Thornhaugh-street, Russell-square London W C 1

A Fracture Clinic

The Grimsby and District Hospital which serves a population of about 140 000 is establishing a special clinic for the treatment of patients suffering from fractures deformities and injuries to bones and joints and has made arrangements with the Grimsby corporation by which the corporation contribute towards an honorarium for the surgeon in charge The corporation will also contribute towards the cost of maintaining patients for whom they are financially responsible and for additional and increased services required in the ancillary departments The hospital is to be approved by the Ministry of Health and the Board of Education for short-term orthopædic cases and the coöperation of Harlow Wood Orthopædic Home is to be obtained for long term cases Public assistance cases are to be transferred back to the local authority institution for the period when no active treatment is required and readmitted to the hospital when necessary Mr R Guy Pulvertaft who is at present surgical registrar in the orthopædic and fracture department of Liverpool Royal Infirmary has been put in charge of the new department his appointment being approved by the Grimsby corporation He will live in the town and will engage only in consulting orthopædic practice The Central Council for the Care of Cripples have undertaken to send a trained organiser to inaugurate an after-care orthopædic service on a regional basis

L C C Hospital Budget

Capital expenditure on general and special hospitals under the control of the London County Council is estimated at £100 000 for the year 1937–38 The budget for maintenance is as follows —

	£		£
General hospitals	560 000	Staff	35 000
Infectious hospitals	150 000	Miscellaneous expenses	3 000
Sanatoria	35 000	Sanitary officers	15 000
Children's hospitals	60 000	Public vaccinators	150
Pathological laboratories	10 000	Diagnosis and treatment of venereal diseases	55 000
Maintenance in hospitals other than those provided by the Council &c.	35 000	Maternity and child welfare	5 000
District medical service	7 000	Midwives service	1 000
London ambulance service	30 000	Other public health services	150

Medical Members of the L C C

Medicine is now represented as follows on the various committees of the London County Council

Education —Dr G A Gillison
Entertainments —Dr Bernard Homa
Establishment —Dr Homa and Miss E Rickards
Finance.—Dr S. W Jeger
General Purposes —Dr F Barrie Lambert
Hospitals and Medical Services —Dr C W Brook Dr S Monckton Copeman Mr Somerville Hastings (chairman) Dr Jeger Miss Rickards (vice) with Dr H Winch and Mr R H P Orde (coöpted)
Mental Hospitals —Dr Barrie Lambert with Dr Doris Odlum (coöpted)
Parks —Dr Barrie Lambert
Parliamentary —Dr Jeger
Public Control —Dr Jeger
Supplies —Dr Barrie Lambert
Town Planning —Dr Gillison.
Welfare of the Blind —Dr Brook (chairman)

St Mark s Hospital, London —The annual general meeting of the governors of this hospital was held on March 18th The Lord Mayor who presided said that during the year 1036 1089 patients were admitted to the wards of the hospital and 1280 operations were performed The out patients attendances numbered 10 999 the highest recorded in the history of the hospital It was hoped that the new nurses home would be ready for occupation next January The home which is the first part of an extension scheme would accommodate 50 nurses and 27 maids and it was proposed to convert the space vacated in the hospital into a self contained block for paying patients and a second operating theatre would be provided and additional public beds The pathological and cancer research, X ray and out patient departments would also be enlarged and modernised The response to the appeal for £50 000 to pay for these extensions had now reached the sum of £14,000 The income of the hospital during the past year had been £14 422 as against £17 300 in the previous year and the expenditure had amounted to £16 270

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Deaf Children (School Attendance) Bill

IN the House of Lords on March 18th the Earl of CRAWFORD moved the second reading of the Deaf Children (School Attendance) Bill which has already passed through the House of Commons without opposition The proposal was, he said that the age for the compulsory attendance of deaf school children, which was at present 7 years should become 5 in the future This was the age of attendance in Scotland and informed opinion in England was unanimous in thinking that the same age should be imposed here Great progress had been made in recent years in the education of deaf children and he was glad to say that the number of deaf children had been reduced, because deafness as a sequela of such illnesses as measles or scarlet fever was being reduced by increased medical knowledge But deaf children required a great deal of education in order to be taught to speak intelligently In normal education the last two years of the educational career were the most valuable, in the case of deaf children it was the first two years because a child, through the influences of the home or the absence of education might either develop a peculiarity of inflection of voice, or insistence upon certain aspects of the voice which were very deleterious to its future, or else it heard wrongly The younger the child, therefore, the better the chance of education So far as he knew the local education authorities the teaching profession, and the medical profession agreed on this point, so that the authority for this proposal was very strong indeed In matters of speech and audition the intuition of a child aged 5 was greater than of one aged 7, and at 7 than at 9 The experience of parents coincided with that of teachers the public authority and the medical world, and he believed that the Bill was unanimously supported In Manchester where the subject was more developed and more studied than in any other town, no fewer than 90 per cent of the children who were congenitally deaf learned to use the human voice perfectly and 90 per cent of those children got employment when they left school

The Earl of LUCAN, speaking for the Government said that it did not seem necessary now to continue this difference on behalf of these young children He was informed that the majority of deaf children aged 5–7 now attended school voluntarily Various organisations connected with the education of the deaf had from time to time urged that legislation to this effect should be introduced and only last summer the President of the Board of Education had said in the House of Commons that he was ready to agree to legislation on the subject provided that it was entirely uncontroversial and that it was supported by local authorities and other organisations The Government were very glad to give this Bill their support The cost of the change was estimated at not more than £5000 a year

The Bill was read a second time

Factories Bill in Committee

The Factories Bill was further considered by a standing committee of the House of Commons on March 16th and 18th

A SAFEGUARDING CLAUSE

On Clause 17 (which provides that in the case of any machine in a factory intended to be driven by mechanical power certain specified parts shall be so sunk encased or otherwise effectively guarded as to prevent danger and that any person who sells or lets on hire for use in a factory any machine intended to be driven by mechanical power which does not comply with the clause shall be guilty of an offence and liable to a fine not exceeding £100), Mr SILKIN moved an amendment to the prov that the clause should not apply to machin constructed before the passing of the Bill into l He proposed that the words "in use" should substituted for the word "constructed"—Sir SIMON opposed the amendment which was negativ —Mr VIANT said that machinery constructed p to the passing of the Bill into law could whoe purchased it be installed in a new factory in s of constructional defects—After further discuss the clause as amended was agreed to

DANGEROUS LIQUIDS

Clause 18 (which provides that certain kinds vessels containing dangerous liquids shall be secur covered or fenced or where that is not practical all practicable steps shall be taken to prevent a person from falling into the vessel), Mr GEOFFR LLOYD, replying to several hon members, said t Home Office officials would examine the position see whether any supplementary provision was nee with regard to movable vessels containing danger liquids and the clause was agreed to

Clause 19 (which deals with safety in relation self acting machines) was agreed to

DANGER TO WOMEN AND YOUNG PERSONS

On Clause 20 (which provides that a woman young person shall not clean any part of a prime mov or of any transmission machinery while the pri mover or transmission machinery is in motion, shall not clean any part of any machine if t cleaning would expose them to risk of injury fr any moving part of that machine or adjac machinery)—Mr G MANDER moved one of a se of amendments which were designed to extend prohibition in the clause to all workers in facto unless the cleaning was performed by means of mechanical device which enabled the person do the cleaning to remain at a distance from the pr mover or transmission machinery which, in opinion of the chief inspector, provided for t safety—Sir J SIMON said that the clause represen an important advance in the law, especially latter part It was no good laying down rules w were in conflict with inescapable practice, or hav a law which in his opinion would not be gener observed The proportion of accidents in fact while cleaning machinery was much higher am women and young people than among men—Mr H DAVIES said that the clause did go a great deal furt than the present law—After discussion the am ment was withdrawn and the clause was agreed to

ELEVATORS AND STAIRS

Clause 21 (which provides among other things every hoist or lift shall be of good mechanical struction sound material, and adequate stre and be properly maintained, and that every h way or liftway shall be efficiently protected b substantial enclosure fitted with gates, the enclo being such as to prevent, when the gates are s any person falling down the way or coming contact with any moving part of the hoist or lift) agreed to with minor amendments

Clauses 22 and 23 dealing with chains ropes li tackle, cranes and other lifting machines were agreed to

Clause 24 (providing that all floors steps st passages, and gangways shall be of sound constru and properly maintained, and dealing also handrails) was agreed to with minor amendm as well as Clauses 25 and 26 relating to safe m of access from workshops and precautions in p where dangerous fumes are liable to be present.

Clause 27, which lays down the precautions shall be taken with respect to explosive or in dust gas vapour or substance was agreed to minor amendment

use 28, which lays down safety provisions with t to steam boilers was also agreed to with amendments as well as two further clauses g with steam receivers and steam containers ir receivers

lause was also approved empowering the chief tor to grant exceptions from some of the safety ions where he was satisfied that they could not ably be applied, another enacting the pre- ns that are to be taken with respect to water- gasholders as well as Clause 33 providing tail for means of escape from factories in case

the House of Commons on March 16th the cal Training and Recreation Bill was introduced ead a first time On March 19th the financial tion in connexion with the Special Areas as agreed to in Report and the Bill was brought l read a first time

March 18th Mr BALDWIN Prime Minister nced that the Chancellor of the Exchequer l open his Budget on Tuesday April 20th

the House of Commons on March 22nd Sir SLEY WOOD Minister of Health presented the ws' Orphans and Old Age Contributory ons (Voluntary Contributors) Bill a measure tend the classes of persons who can become d as voluntary contributors for the purposes dows orphans and old age contributory ons and otherwise to amend, in relation to tary contributors and women engaged in n excepted employments the enactments ng to such pensions and to health insurance nend Section 30 of the Widows Orphans Old Age Contributory Pensions Act 1936 ection 4 of the Northern Ireland (Miscellaneous sions) Act 1932 and for purposes connected the matters aforesaid

e Bill was read a first time

QUESTION TIME

WEDNESDAY MARCH 17TH

British Hospital Ship in Spanish Waters

MANDER asked the Secretary of State for Foreign which of His Majesty s ships would maintain with His Majesty s diplomatic and consular repre tives at Valencia Bolivia Palma and elsewhere in sh ports during the next few weeks —Mr EDEN d: It has been arranged that His Majesty s hospital *Maine* together with at least one destroyer and one ship shall be available on the north-east coast of and Majorca for the purpose to which the hon ber refers. In addition to these I understand that her is at present available

Alcohol and Road Accidents

WILSON asked the Home Secretary whether in aining of the new 800 police patrols, any instructions l be given in the steps to be taken to make effective dvice in the Road Code to motorists against taking ol during or before driving —Mr GEOFFREY LLOYD r-Secretary Home Office replied I think the hon er must refer to the paragraph which says: Before the road be sure that your alertness or sense of on is not affected by alcohol or fatigue I do not this is a provision which could be very well enforced e police

Lunacy and Mental Deficiency Statistics

RALPH GLYN asked the Minister of Health the nt number of certified lunatics in the asylums of nd and Wales under the administration of county rities; and how these figures compared with the s in 1926 and 1913 —Sir KINGSLEY WOOD replied mber of certified mental patients in mental hospitals ded by local authorities (i e county and county borough councils and a certain number of non-county borough councils) in England and Wales was as follows

1937 (Jan 1st)	123 609
1926	107 836
1913	103 842

Sir RALPH GLYN asked the Minister of Health how many mentally-defective individuals were under the care of mental hospitals and asylums and how many were boarded out under licence and how these figures compared with those of 1926 and 1913 —Sir KINGSLEY WOOD replied: The Mental Deficiency Act of 1913 did not come into operation until April 1st 1914 but the numbers of mentally defective patients under care in institutions provided under the Mental Deficiency Acts 1913–1927 and on licence are as follows:—

	In institutions	On licence from institutions
1936 (Jan 1st)	37 810	2 437
1926	20 207	Not available

THURSDAY MARCH 18TH

Holidays with Pay

Mr ROWSON asked the Minister of Labour the names of the members of the commission to inquire into the question of holidays with pay and when they would commence their duties.—Mr ERNEST BROWN replied I hope to be able to make a statement on this matter very shortly

Textile Industry and 40 hour Week

Mr WILLIAM ROBINSON asked the Minister of Labour whether any instructions had been given to the British delegation to the world textile conference at Washington as to their attitude in the event of a 40 hour week in the textile industry being proposed by some other delegation —Mr ERNEST BROWN replied The conference at Washington in April is a technical conference the object of which is to consider all those aspects of the textile industry which directly or indirectly may have a bearing on the improvement of social conditions in the industry The question of adopting a convention for a 40 hour week for the industry is to be considered at the annual conference of the International Labour Organisation in June The attitude of H.M Government towards the latter question was stated in my speech at the annual conference last year

Birching of Young Boys

Mr MUFT asked the Home Secretary whether he was aware of the public concern caused by the action of various magistrates in ordering the birching of young boys for minor offences and whether he would institute an inquiry into the desirability of abolishing this form of punishment —Sir JOHN SIMON replied: There were 164 cases of this punishment being ordered in juvenile courts in 1930 and 218 cases in 1935 This is a subject on which many people have strong views on one side or the other and in which the practice of different juvenile courts differs widely I have therefore decided to appoint a small departmental committee to consider the whole matter If however the report of such a committee is to be of value its members must be selected with a view to securing that they approach the subject with an open mind and I shall not be able to make an announcement of the composition of the committee without full consideration of the appropriate personnel

Hours of Employment of Young Persons

Mr WALKDEN asked the Home Secretary whether he had given consideration to the report of the departmental committee on the hours of employment of young persons in unregulated occupations and whether he intended to give legislative effect to the committee s recommendations

Mr DENMAN asked the Home Secretary whether he had considered the statement in the report of the Committee on Hours of Employment of Young Persons in unregulated occupations that it was essential that immediate steps should be taken to afford statutory protection to such young persons whether he would introduce legislation without unnecessary delay and whether in particular he would adopt the recommendation to extend the current Factories Bill so as to include young persons employed in connexion with factories, docks, and warehouses —Sir JOHN SIMON replied The report of the committee, which was only published a week ago is now under careful consideration but I regret that I am not in a position at present to make any statement

Mr DENMAN Can my right hon friend answer the last part of my question referring to the current Factories Bill Are the Government making up their minds rapidly on that point ?

Sir J SIMON I agree that it would be useful to get a decision in time for the present Factories Bill, but the report is a most important one, it was published only last week and it must be examined thoroughly

Night Work and the Health of Juveniles

Mr DENMAN asked the Minister of Health whether he had or will obtain from approved societies any information as to the effect of nightwork in factories on the health or physique of young persons either at the time or in subsequent life —Sir KINGSLEY WOOD replied I regret that I have not the information desired by my hon friend, and the records of approved societies do not contain the necessary material from which the information could be obtained

Influenza and the Common Cold Medical Research

Mr LEES-JONES asked the Lord President of the Council (1) over what period experiments and research had been taking place, with the assistance of the Medical Research Council towards finding a medium for the prevention and cure of the common cold and influenza, and what the cost had been to date, and (2) what progress had been made by or under the ægis of the Medical Research Council within the past 12 months towards finding a medium for the prevention and for the cure of the common cold and influenza —Mr RAMSAY MACDONALD replied Research on influenza and the common cold has been assisted by the Medical Research Council from time to time In particular the investigations into influenza which are now being made by the Council's own staff at the National Institute for Medical Research have been in progress since 1933 An account of recent progress is given in the annual report of the Medical Research Council for the year 1935–36, presented to Parliament and published last Tuesday During the past year there has been further confirmation from different parts of the world that the virus originally isolated at the National Institute for Medical Research in 1933 is the infective agent which causes epidemic influenza, and on this basis attempts to devise preventive measures are being continued Substantial progress has been achieved by these scientists working in the service of the British Government, and there is considerable ground for hoping that a satisfactory means of producing at least temporary immunity will be evolved Earlier methods of inoculation against influenza have been unsatisfactory, because they were not based on the accurate knowledge, which is now believed to be available, regarding the nature of the causative agent

The Council are not at the moment supporting any direct attack upon the common cold, but the problems are closely related, and an advance against the one disease is likely to assist attack on the other A statement which has been made in the Press to the effect that the Council has, as a matter of policy abandoned work on the common cold is without foundation It is not possible to state the cost of this investigation separately from that of other work involving the same personnel and equipment

Sale of Unsuitable Spectacles

Mr ROBERT TAYLOR asked the Minister of Health if he had any information as to the detrimental effect caused by the wearing of spectacles sold by certain stores and by pedlars with no qualifications as opticians, and if he proposed to take steps to prohibit such sales —Sir KINGSLEY WOOD replied I have no direct evidence of damage caused by the wearing of the spectacles referred to and I have no power to prohibit their sale So far, however as insured persons are concerned it is proposed to make regulations to the effect that spectacles provided by way of additional benefit can only be obtained fr opticians recognised by a committee to be set up under regulations

The Construction of Gas Masks

Mr CREECH JONES asked the Home Secretary what the flocculent material being used as a filter for smo in the gas masks now being manufactured in Blackb for free distribution to the civilian population, what (if any) had been the percentage of smoke wh had passed through this material when subjected experiments —Mr GEOFFREY LLOYD replied T material employed as a filter for smokes in the gas ma now being made at Blackburn for distribution to civilian population consists of a mixture of wool asbestos Extensive tests with toxic smokes have pro that the respirator will afford protection against all poison gases under the conditions which would arise practice

Death Following Vaccination

Mr GROVES asked the Minister of Health whether had made inquiries into the death of Frank A Bar aged 24, of Grantham road, Manor Park, which attributed by the Ilford coroner to the effects of vacci tion, what was the source of the lymph used, whet rabbits had been used in its manufacture, whether young man's employers made vaccination a condit of employment, and, if so, whether, under the Workme Compensation Act, his widowed mother would rece damages —Sir KINGSLEY WOOD replied The ans to the first part of the question is in the affirmat With regard to the second and third parts, I am infor that the lymph used was obtained from a commer firm, and I understand that rabbits were not used connexion with its manufacture I have no informat as to the fourth part of the question, and I am unable express any opinion in regard to the last part

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK EN MARCH 13TH, 1937

Notifications —The following cases of infec disease were notified during the week Small p (Ripley, U D, Derbyshire), scarlet fever, diphtheria, 1086, enteric fever, 30, pneum (primary or influenzal), 1209, puerperal fever, puerperal pyrexia, 110, cerebro-spinal fever, acute poliomyelitis, 3, acute polio-encephalit encephalitis lethargica, 3, dysentery, 25, ophth neonatorum, 81 No case of cholera, plague, or typ fever was notified during the week

The number of cases in the Infectious Hospitals of the Lo County Council on March 16th was 3336 which inclu Scarlet fever 857 diphtheria, 1060 measles 23 who cough 606 puerperal fever 20 mothers (plus 14 b encephalitis lethargica 282 poliomyelitis 1 At Margaret's Hospital there were 16 babies (plus 5 mot with ophthalmia neonatorum

Deaths —In 122 great towns, including Lon there was no death from small pox or enteric fe 9 (0) from measles, 3 (0) from scarlet fever, 2 from whooping-cough, 34 (6) from diphtheria, 48 from diarrhœa and enteritis under two years 144 (12) from influenza The figures in parent are those for London itself

Birmingham reported 3 deaths from measles Fatal of whooping-cough were scattered over 15 great towns Mi brough had 3 Fatal diphtheria was reported from 20 towns, 3 each from Bradford and Sheffield

The number of stillbirths notified during the was 305 (corresponding to a rate of 46 per 1000 births), including 46 in London

---

MIDDLESEX HOSPITAL —At a meeting of board of this hospital on March 17th it announced that the anonymous donor of the n home had given a further £50,000 for its extension, bringing his benefactions to the hospital to £400 000

Welsh National School of Medicine

Dr J Hardstaff West has been appointed lecturer in anaesthetics Dr T J Hennelly lecturer in mental diseases, and Dr F R Bei ley lecturer in dermatology and lecturer in venereal diseases (male)

Medical Superintendents' Society

Dr J D Ewart presided at the annual dinner of this society which was held at the Langham Hotel, London, on March 20th It was his last chance to preside, as in two weeks time he is retiring from the Booth Hall Infirmary for Children Manchester, which he has ably superintended for so long Sir Cuthbert Wallace proposing the toast of The Society told the story of the development in his time of his own hospital, a period coinciding with the life of the society Both then and now there were eight surgeons and eight physicians but the two special departments had developed out of knowledge pathology had grown out of its one small room into an institute, and the X ray department was now more expensive even than the surgeon He spoke of hospital construction as a compromise in which the help of members of the society was required Dr D'Ewart, in response, inquired why one surgeon never used the same kind of knife as any other surgeon and indicated how the surgeon could be bluffed At Booth Hall the first X ray department was pushed into a housemaid s pantry and a neighbouring chemist brought in to work it Dr W A Ramsay, another Manchester superintendent proposed The Guests, giving each sympathetic but searching attention he condoled with the medical press on having to deal with writers who drew sweeping conclusions from a series of five cases two of which were definitely proved Dr Adolphe Abrahams and Dr Ernest Ward responded, the former remarking pitifully that man is the only animal who indulges in after dinner speaking, all the others have the sense to lie down and go to sleep Representatives of voluntary hospitals were apt to speak of the *threat* of State control by the stroke of a pen The word, he thought, should be *promise* he was more and more impressed by the organisation resources and wealth of material of the rate aided hospitals and there must surely come a time when the resources of all the hospitals would be pooled At intervals during the dinner Mr Michael North intervened with entertainment

Fractures and Industry

The waste of working time and of evolv paid in compensation after accidents is so impor fluenza the Minister of Health and the Home Secretar based on th up a committee to consider how they can b o available Mr R S Hudson Parliamentary Secretary t y of Health, spoke of the work of the new comm ent supp cheon given on March 10th by the Industrial We , but the He asked for the influence of the society in ga nst the ou erest both of employers and of workers associa er A st ustrialists had in some cases been sufficiently o effec with the amount of suffering caused by injuries, done with the loss of time and wages involved as to contribut substantially to the cost of treatment At the same luncheon Mr H E Griffiths who is organising the treatment of accidents as it is to be carried out at the new Albert Dock Hospital, under the management of the Seamen s Hospital Society and who has been investigating in the United States the methods in various industrial centres said he learnt four main lessons of which the first is the importance of segregating all fractures under one control the standard of training of the ambulance service should be high and rehabilitation should start immediately after the accident and be kept constantly in the forefront Good feeding he decided is the most important of all At the Albert Dock Hospital out patients are to be treated from 9 A M to 6 P M and to be given three meals a day There is to be a shock room wards with adjacent dressing rooms and a training room with gymnasium and swimming bath The im point, he said was to keep the injured part at and it is possible to do this painlessly by modern m for which he paid a tribute to the genius of Lore iz Drawing attention to the vastness of the proble had to be considered Mr Hudson said that in 19 than 1 300,000 accidents were treated at hospi Great Britain, these included 200 000 cases of fi In 1934 accidents in industry had caused 400,000 l cases and had involved the payment of about £4,(in compensation to the victims
